the instant the echo is received). The difference in freq and the freq
ramp rate give distance to object. Obviously, ma range is given by
chirp length, the farthest echo must return before the next chirp.

==========
With a bit of 'home-brew' initiative , discarded floppy disk drives are a
good source for stepper motors. Especially the ancient 8 inch drives ,still
available @ flea markets, have powerful stepper motors.
But also the smaller motors from 3.5 inch and the older 5.25 inch floppy
drives can be very useful.
However ,in order to smoothly tune a magnetic loop (especially when used on
160 & 80 metres)
you have to check the change of angle per step. On the lower freq ham
bands magloops are veeeeery narrow band and have to be retuned at
practically any change of frequency at which 1 step of the motor might be
too much. This can be overcome be inserting a coaxial reducer 3:1 or 6:1
between motor and variable capacitor.
These reducers are still available from a few retailers or otherwise from
flea markets.

If a magloop has a variable vacuum cap the change of angle per step is not a
problem ,however the stepper motor might not have enough 'oemff' to rotate
the vacuum cap. ,so a reducer (also increasing torque) might still be the
answer. This obviously is not relevant to the ISOLOOP.

Okay, then would you prefer to use a 28V power supply. If we're talking only about simplex channels on the 2-m band that leaves us with a bandwith of about 500kHz That allows the Q to be around 300. and the amp operating in the C class. say twenty watts. That should leave me with the impedance of 15 ohms. would you prefer this to the previous version ?

3149. FS: Litz, bifilar, trifilar, multifilar wire

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-16 21:07:55 UTC
From: Brad Thompson <brad.thompson@valley.net>
Message-ID: <3B02EC2A.929C5D56@valley.net>
Source record: 52646

FS: Litz, bifilar, trifilar, multifilar wire

As an experiment, I'm offering antique-radio repairers and
amateur-radio project builders 10-foot lengths of the following
exotic wire for $3.00 each length postpaid (US only).

Use Litz wire to rewind damaged RF coils, and multifilar
wire to assemble baluns, transmission-line transformers,
and small power inductors. Here's what's currently available:

(Number of conductors conductor gauge, construction, color code)

Bifilar wire:

2 cond. AWG#34, parallel-bonded (i.e., untwisted), red/green
2 cond. AWG#32, twisted (6-8 twists/inch), red/green
2 cond. AWG#28, parallel-bonded (i.e., untwisted), red/green*

Trifilar and multifilar wire:

3 cond. AWG#32, twisted (6-8 twists/inch), red/green/amber
4 cond. AWG#33, twisted (6-8 twists/inch), red/green/white/blue
13 cond. AWG#25, twisted (7 twists/foot), one green/12 red

Litz and other wire:

1 cond. AWG#36 nyleeze/single nylon fabric wrap
Litz, 24 strands AWG#44, single polythermaleeze/single nylon fabric wrap

Litz, 25 strands AWG#38, single polythermaleeze/single nylon fabric wrap

Notes
-----
* Quad polythermaleeze nylon insulation

To get an idea how much wire you'll need to rewind a coil, measure the
coil's
diameter and multiply by 3.14 to get the length of a turn. Then,
multiply
by the number of turns to get the total length (allow a few inches extra
for
making external connections).

If you need longer lengths of wire or need more information, please
contact me.

Source record: 52498

Thank you both Frank and Matt. I'll probably go with one of the surplus ones that Matt suggested. As for the step angle, the original was a 400 s/r and it was driving a pully which I would estimate gave it maybe a 6:1 ratio. I see that a good number of motors are 200 s/r so I might just increase the size of the pully wheel on the tuning cap to achieve the same ratio. And it is indeed an air-gap capacitor, which spins very frictionlessly on nylon bearings, so at least horsepower won't be a factor.

Thanks again, I really appreciate the info!

Source record: 52503

Hi Adrian,

If you are talking about something that narrow and FM then I would definitely go with a lumped element or cavity match.

The Q that you are interested in is the loaded Q of the network. You may easily have an unloaded Q of 300 or more. Some of your loss will be determined by the ratio of loaded to unloaded Q in the network. Larger ratios are better. If at all possible you want to keep the ratio above 10.

If your devices will take it the higher the supply voltage the better. Generally you see people talking about keeping the breakdown voltage greater than 4X the loaded output voltage. For a 28 volt supply and a high Q tank you could have 50 volts peak to peak on the output. You device would have to be good to 200 volts to be "safe".

From here on you are going to need data on the device you intend to use. Stability will be the biggest problem. Normally people seem to use computer models to get the device stable. Of course if you have enough parts you can do it by trial and error. Are you planning to use a FET or a Bipolar part ?

Scott,

I am unfamiliar with your Yaesu, so I cannot comment on whether it actually has DSB or if you have a failure. I would suggest you look in the owners manual to see what it says.

DSB used to be an inexpensive way to transmit SSB. The only real down side is that you are transmitting both sidebands. DSB with the carrier injected is AM. DSB with the carrier suppressed is DSB sideband.

I agree there seems to be no reason to include DSB if you already have SSB!

So, we should praise you for being a lawbreaker? If you know so much about electronics and ham radio why don't you get a license? The code speed requirements have been reduced to the point that a novice can learn enough in a week to pass. The theory requirements are not too hard, certainly simple enough for one who "understands" electronics. Why don't you become legal? The FCC does not interfere with our operations. We are not subject to a fine each and every time we turn on our rigs, you are though!

Zack,

I have etched boards of all types. I have started with something as simple as a "Sharpie" to masking tape. I have also tried transfer paper. They all have been successful except for transfer paper. There seems to be a wide variety of different requirements for using transfer paper. Maybe I have not tried often enough. They must start with a good xerox copy, of exactly the right density (or darkness). The iron temperature must also be correct. Then, if you are lucky, or have made offerings to the correct gods, it might work! For my money, masking tape was the easiest. Or try to find a set of General Cement rub down circuit elements!

>
>73
>
DSB is more difficult to tune in than SSB if you don't reject one of the
sidebands in the receiver. In SSB you can tolerate a little slop in the exact
carrier frequency and the audio comes out "quacky" but still intelligible. In
DSB, if you're slightly off you get both "quacky" sidebands interfering with
each other.
To get 'sideband diversity' (if there is such a thing) you need to select either
one or the other sideband, whichever is better but not both.
This is why I use CW.

What are the man-1a. I have some old red led 7 segment displays that
are about the size that will fit in a 14 pin dip IC socket. Been a long
time and don't recall the details of the man series . Also the decimal
point may be where the A comes in.
Think the ones I have are on the right. Let me know if you have not
found any. Maybe we can get together and discuss it sometime on 75
meters.

I was wondering the same thing, but at the moment I don't feel like
digging to find out. It would just be easier for the poster to give
us the size. I remember buying some very small 7-segment readouts
in the early seventies, like calculator readouts but single-digits,
and those might be a problem finding at this point.

If they are the size that fits into a 14-pin socket, a replacement
would be quite easy. I don't know if the pinout is completely
standardized, but I've traced unknown 7-segment readouts
only to find them matching a standard pinout. The key point,
other than the size and pinout, would be whether it's a common
cathode or common anode readout, and which side the decimal
point is on. There might be cosmetic difference if an exact
replacement can't be found, but then one could always replace
all the readouts with the same kind.

I would spend some time looking for info if the original
poster posts about the size of the readout.

3169. Transceiver in Ford Explorer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-18 13:16:56 UTC

Greetings,

I'm trying to mount a 10m transceiver in my Ford Explorer. It is a stick shift, so "hump mounts" are out. It looks like it would fit under the dash slightly left of center, but the mounting surface is plastic, so probably wouldn't be secure. Anyone out there with an Explorer? What did you do? I'd actually like to mount TWO transceivers in there, but I can't even find a place for one.

Before you go drilling any holes, try it out. Ford Explorers are
notorious for NOISE, bad enough that only S9+ signals can be copied.
Check the NG archive in deja.com for a long history of Explorer noise
issues.

3172. weller soldering gun problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-18 19:42:02 UTC
From: "Charles T. Young" <ctyoung@mtu.edu>
Message-ID: <tgauoapnbci29f@corp.supernews.com>
Source record: 52519

Hi:

I have a Weller soldering gun that keeps giving me trouble.
After I use it a couple of times, it will become very slow to heat up.
I think the problem is the electrical connection to the tip.
This particular Weller has screws to tighten the tip. But the
slots in the screws get enlarged, then it is hard to tighten them,
so I have to use pliers on the screws, etc.

Has anyone found a solutions to this? I buy these Weller guns
so seldom that I don't know where to get them anymore, and besides,
the problem is in the screws, not the whole gun. I bought a Weller
gun about 30 years ago that had nuts you tighten, it worked much
better, but I don't know where to get that now.

Please reply by email to ctyoung@mtu.edu

They're probably corroding, not enlarging. Use some anti-seize on the
screws.

Hi Adrian,

Once you pick a manufacturer they probably will have application notes
that will help you on the next steps. At the very least they should
have the basic input and output match parameters you will need.

It is oxidation causing the resistance to go up.
Avoid the temptation to tighten the screws when
this happens. Try loosening the screws, then
gently retightening them to cure the problem.
Continually tightening leads to bigger problems
in a hurry.

Great! Not all of the Fords have the problem to the same degree, it's
caused by a fuel pump in the tank ... and is expensive to remedy.
It's not so noticeable at higher freqs so maybe 10 meters is just high
enough. I just didn't want the guy to drill any holes only to find
out he couldn't hear diddly. I'm sure your post will brighten his
day.

DSB works well when the receiver contains the circuitry to extract phase information from the sidebands such that a properly phased carrier can be reinserted. Most commercial DSB broadcast systems - there are such things - transmit a small pilot carrier to facilitate proper carrier reinsertion.

A GE engineer named Costas did some pioneering work on advanced DSB transmission and reception systems back in the 50's while I was in grad school. I seem to recall that he published in one of the amateur magazines an article on the "Costas System" of DSB. Maybe someone with better recall can furnish a reference.

I make no claims for the superiority/inferiority of DSB vs AM vs SSB. But DSB systems do exist and are said to have advantages under certain conditions.

Look up behind the plastic and see if there is anything substantial such as an-
other layer of metal or plastic. If you don't smoke, you might remove the ashtray and use the screw holes that held it in. This is what I did on a Lumina
that had a center console. I discovered that this was an excellent solution.
When I trade the car, I will replace the ashtray assembly and no one will be the wiser.

I suggest removing the screws and tip and cleaning it all with sandpaper. Look for blackened or glossy surfaces and polish them all. It should work great after that. Any part the tip supports touch should be shined up and clean.

Source record: 52530

Hello...

The MAN displays were one of the first 14 pin dip, 7 segment displays. ...Mid to late seventys or so. Anyhow, each segment is composed of a number of tiny led chips in-line. Much brighter and crisper than contemporary's single led illuminated segment type.

The things look different from most displays. The clear red window material comprises the entire structure. That is, (probably) the strings of LEDs were laid-out in the 7 segment pattern on a substrate with leads exiting the back. The LED/substrate/lead assembly was then cast in a rectangle of (nothing but) the clear red plastic. The result was about .1" thick, excluding leads.

I have some later versions, but unfortunately, can't use them as they have built-in counters and/or latches. They are built the same way - You can see the logic chip through the red plastic.

I haven't dug out the (yellowed) data sheet lately, so don't remember the pinout/polarity. I expect I could locate a current display that would work OK, but I kinda like the looks of the MAN and would like to match what I have...

The decimal placement is of no concern since the readout has 4 other fully functional MANs and only one D.P. is used.

TIA..

I use boards pre-coated with photoresist. Circuit Specialists in the Phoenix area has carried them for some time, and now I see that DigiKey also carries them. (Note: C.S. claims theirs are 1 oz copper, but in fact they are 1/2 oz...at least all I've gotten from them.) You can print a transparency on an inkjet printer (generally better than laserjets) and expose with fluorescent lighting. You can do all the "darkroom" stuff in dim room lighting. I regularly do 10 mil lines/ 10 mil spaces this way, and can do 8/8 pretty reliably. If I get photo artwork made, I can do down to 5/5. I've done fine-pitch (0.5mm) SMT this way. If I watch the process carefully, the success rate is well over 90%, but I do have to remind myself to cross all the t's and dot all the i's...things like letting my exposure lamp warm up at least five minutes before doing the two minute exposure. (Impatience makes waste.)

There have been innumerable discussions of home PC board making over on sci.electronics.design.

73,
Tom

Source record: 52533

Hi all,

Well I could use some help
I was surfing the net and came across Magnetic Loop Antennas (looks like
fun) so I set out to make myself one.

located the page on homebrewing air caps from JO21FF (looks easy)
Here: http://www.qsl.net/mnqrp/Loop/Mag_Loops.htm

Now to remote control the cap with a stepping motor
(Brick wall) I never even herd of a stepping motor before this.
after some reading I find out that printers have stepping motors(cool I have
some old printers)

This is what I pulled from one of the printers:
Stepping Motor
#PJJQ148ZA-K
Volt - 4V
Coil - 5ohm
DEG/STEP - 1.8
6 - WIRE
KYUSHU MATSUSHITA ELECTRIC CO. LTD.

It's big and heavy it should work
Now for some help
How in the world do you control this

If you can help me I would be grateful
Thx
David

3187. Program RJELINE4.exe

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-19 21:53:13 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9e6q00num1@plutonium.btinternet.com>
Source record: 52534

NOW AVAILABLE, Program "RJELINE4.exe"

FULL ANALYSIS OF PERFORMANCE OF BALANCED-PAIR TRANSMISSION
LINES, 20Hz to 1GHz.

This program is an improved version of RJELINE3.exe. Extra output
data and user operating facilities have been added and the
extensive introductory notes have been rewritten. All the original
facilities have been retained.

Study all types of line from 50 Hz HV power distribution, overhead
and underground phone lines, antenna ladder lines, 100-ohm figure
of 8, to UHF high-power lecher-lines.

Input data is a line specification, Zo, conductor diameter,
dielectric loss factor, velocity factor, frequency, line length.
Also series resistive and reactive components of the terminating
impedance.

Output data is in 3 sections: Line Characteristics, conductor
spacing, R,L,C,G, attenuation, propagation velocity, Line Input
Impedance in various forms, and Line Performance, reflection
coefficient, SWR, actual line loss, power transmission efficiency,
resonant Q factor, etc.

Exact classical transmission line formulae used. Skin and conductor
proximity effects are taken into account. DC and AC conductor
resistance can be compared and observed to diverge with increasing
frequency and with closer conductor spacing.

Applications:- Transmission line design and design of line
transformers intended for complex terminations R+jX. Educational.

This program has been produced to the highest standards. Use it to
check accuracy and reliabilty of other transmission line
calculations and calculators.

Program size 75.6 Kilobytes. Download RJELINE4 in a few seconds.
Not zipped up. Run immediately.

The best trick I saw was using one stepper as a generator to run
a second stepper. A local ham brought one to a club meeting. Not as
much torque as running the normal way, but it should be enough for
a tuning cap and you can't beat its simplicity.

3189. Iambic Morse Keyer - simple and accurate

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-19 22:17:14 UTC
From: Owen Duffy <owen@oda.com.au>
Message-ID: <3B06F0EA.51DB4727@oda.com.au>
Source record: 52536

Here is a simple approach to an iambic morse keyer that is well suited to integration in a home brewed transceiver / transmitter.

Power consumption is very low and board space is small, which suits it also to QRP / portable configurations.

Despite using less than a dozen parts for the essential keyer (and another 4 parts for the regulated power supply), it gives nothing away in terms of performance and accuracy for an iambic keyer, it does not require alignment and does it require any sophisticated equipment for construction.

Have a look at it at http://www.owenduffy.com.au/electronics/pik/pik.htm .

You can't get them anymore. (Well, you can get them in photo shops in Europe.)(Although much more mercury is introduced into the environment through fluorescent tubes, switches and coal, the batteries had to go also.)

My suggetsion- I have done this with a Gossen light meter -- use a low dropout 2.7 volt regulator from Linear Tech or Toko with a pair of '76 batteries. The overhead is quite low and the SMT devices can be easily soldered into place.

Not specifically, but Radshack has a helmet-mounted one for $24.95 (along with several other styles) that I use on my HTX-202, which shares the same pin pattern as many FRS radios. Maybe you can get ahold of one of these from a friend and take a peek, or even repair it if it's broken.

3197. Philips TEA5551T & TDA1572T

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-20 17:25:58 UTC
From: Sverre Holm <sverre@ifi.uio.no>
Message-ID: <Pine.GSO.4.21.0105201921120.12585-100000@granvin.ifi.uio.no>
Source record: 52544

I am planning to make a surface mount ham receiver and would like to make it as small as possible. Does anyone have any experience with any of these chips:

TDA1572T AM receiver (IF output should be possible to add a BFO etc)
TEA5551T One-chip AM radio (up to 40 MHz), includes AF amplifier

- or any other similar chip that integrates all or most of the stages for an AM receiver.

I think they use a 455 kHz IF frequency so they should give acceptable image rejection for the 80, 40 and 30 meter bands. For higher bands one could use a pre-converter down to e.g. 5.5 MHz first.

Source record: 52545

Hello--

I'm offering a batch of microwave-grade printed-circuit
board laminate. Previous batches have sold quickly, so
e-mail me to reseve your choices to avoid disappointment.

73,
Brad AA1IP

****

Taconic Plastics, Ltd. p/n TLE-95-0100-C1/C1

PTFE/glass dielectric of 0.01 inches thickness and dielectric
constant of 2.95 nominal. Laminated with 1-ounce copper on both sides.

Supplied in 9-3/8 by 18-inch panels separated by sheets of anticorrosion

paper (some edge discoloration is present). Note that this thin and
flexible laminate will require extra care in processing.

Price: $10.00 per piece; or $20.00 for three pieces, plus $4.80 for
insured priority-mail shipment (U.S. only). Please add $2.00 postage
for each increment of three additional pieces (e.g., postage for six
is $6.80; nine is $8.80, etc.). Canadian purchasers, please inquire for
postage.

Also available in boxes of 50 sheets for club projects-- please inquire
for price and postage.

****
I accept payment via personal or cashier's check or money order drawn
in U.S. dollars and made payable to "Brad Thompson", or via certain
credit cards.

Warranty policy:

If you purchase these boards and find them unsatisfactory upon your
visual
inspection, notify me within seven days and return in as-received
condition
for a full refund of your original purchase price (you pay return
postage).

This material is subject to prior sale and is supplied as-is, as
new-old-stock
(NOS) merchandise, with all responsibility for safe and successful
application

residing solely with the purchaser.

Thanks. Actually, pulled the ashtray and it's mounting frame in order to investigate what problems I'd have drilling a hole. When it was out, I thought I'd just try the transceiver in the opening for fun. It almost fit, would require just a little trimming of the plastic tabs on each side. I think I could fabricate an L bracket for both sides of the box using the screw holes intended for the microphone clip to hold it on. Then, the screws that held the ashtray frame could be used for mounting. I won't miss the ashtray, (I quit smoking 20 years ago.) except for it's lighter socket, which I can mount elsewhere.

I already tried the transceiver just sitting in the seat, and the noise seemed to be no more of a problem than it is with the 2m rig under the same circumstances. Maybe I'll scrap the radio and mount the 2m rig there. :-) Just have to figure out how to get the original radio out. I know it has something to do with those four holes around the bezel, but try as I might, I can't get it loose.

FM can be demodulated using slope detection and, by purposely causing the regen detector to break into oscillation, SSB and CW can also be demodulated. There may be other reasons that superregens are not suitable, but not that it can't demodulate the signals.

We finally took the advice of several hams and made a bulk purchase of transmitting crystals from Jan's in order to include them with our Peanut Whistle Two 40 meter QRP CW transmitters for those who don't have a junk box of assorted crystals. We chose the internationally recognized QRP frequency of 7.040 MHz. And we are selling the crystals to you AT COST with the purchase of a Peanut Whistle Two transmitter. Sorry! No individual crystal sales. They are exclusively for PW-2 purchasers. The cost of the Peanut Whistle 2 without crystal is $19.95 plus s&h. For the Peanut Whistle Two that includes the 7.040 MHz transmitting crystal...ONLY $29.95 plus s&h. You're invited to look at photo's of the PW-2 and see further details at our website: http://qth.com/dwm

Of course, if you put a superregen receiver into continuous oscillation,
it's no longer a supperregen but just a regenerative receiver. Though
nothing comes to mind at the moment, I thought there were reasons why
superregens helped to pioneer the higher frequencies rather than
the regen.

The problem with slope detection on a superregen is that they tend
to have wide bandwidth. Probably fine for wide deviation like
FM broadcast and TV audio, but it will give low recovered audio
when receiving narrow deviation FM as found on the ham bands.

Years ago, the attempts on narrowing the bandwidth of a superregen
focused on a better coil. Use a high-Q coil, or build the tank
circuit out of coax. But most superregens were really simple,
using the same active element as both the regenerative detector
and the quench oscillator for it. That does not give much control
over the quenching of the circuit. You've basically got a square
wave running at just above audio frequencies putting the regen
detector in and out of oscillation. Except in the very early
days, like when the superregen was invented by Armstrong, did
anyone give much consideration to having a separate quench
oscillator. And I'm not even sure whether the original
superregen used a separate quench oscillator or was self-quenched.

Charles Kitchin has done some work with superregens in recent
years. A number of his articles on superregens have appeared in
Communications Quarterly, QST and QEX, and I've listed the articles in
previous posts. He says that the quenching is critical to

getting a narrower bandwidth in the superregen. The waveform is a consideration. One of his articles had a control to adjust the quenching, though it was the usual self-quenching circuit, and he gives great claims for reception of narrow deviation FM.

3213. Yaesu FT50 - setting VFO to PMR446 channel

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-21 19:33:22 UTC
From: Richard <Dickus@dial.pipex.com>
Message-ID: <9ebqp8vot1@news8.svr.pol.co.uk>
Source record: 52559

Can anyone help with the following problem:

I have an FT50 which I want to set to a PMR446 channel frequency e.g.
Channel 2 = 446.01875

When setting VFO the closest I can get is 446.0125 (step of 12.5) or 446.020
(step 5.0).

The Yaesu has wideband mods applied and is set to "Freeband" (not sure if
this matters) and I'd like to be able to talk to PMR446 users on specific
PMR446 channels.

Is there any way of setting precise channel?

TIA

Wonder if anyone can help me. I have a sharp satellite tuner can which i use to recover audio from a microwave source. I dont have a part number for this item, all that is on it are two different numbers.

Prob, ser no. and something else.

Wondering if anyone would have any idea on the part number, or even tell me which receiver it would happen to come from.

Numbers are f1412a
and Bsfa75g08

Know its a very long shot, sharp(who its made by) cant (wont) help me on this one.

The can has 8 connections on the bottom. Audio comes from the 5th pin along
from the f-connector. Know its v.vague and am grasping at straws, but this is my last hope.

Thanks

Jimbo

I'm currently halfway through building a simple ultrasonic pulse radar, from a design in the book "Electronic Projects for Experimenters", by Robert Penfold, published by Babani.

This consists of a hand-held box containing ultrasonic Tx and Rx transducers, oscillator and detector circuits, batteries, and a row of LED's to indicate distance of targets, same concept as an A-scope but using brightness to indicate signal strength. I will fit sockets to allow connection to an oscilloscope for a proper A-scope display.

Range is stated as 5 metres.

When I get a 'round tuit' I might write a letter to Practical Wireless about amateur radar.

FS: by Fred WA5WZD
Reduced price, need the cash! ICOM IC-706 Mk1 in excellent condition
with box and packing. Power cord (about 6 ft) and all written material.
Included is a good working screwdriver antenna with the mounts used on a
pickup tool box and braces. Also included is an MFJ-815B HF peak reading
SWR/Wattmeter. This is the cross needles meter and makes tune up very easy.
The tuning system uses the inductor shunt at the base that allows tune up
any where within the HF range instead of having to switch caps with relays.
I'm an ex ICOM manager in Dallas so it's been treated with kid gloves.
Most operation has been on 40m and 2m ssb.
Asking $650 for the package and buyer pays a nominal shipping fee of $25
insured. Fred fred-palmer@msn.com 940-321-2029

Up until a few (?) years ago the Weller "barrels" were plated copper,
and these always worked well. Then Weller modified the design
substituting alum parts and these will always oxidize and will never
last like the early ones which they made for decades. Unfortunately,
your experience is typical for the current versions of Weller guns.

In that case how does the radar know the difference between something stationary a long distance away (when the returned frequency has a large -ve offset to the current transmitted freq because of the time delay) and an object which is close but moving away at a high speed (here the returned frequency has a large -ve offset to the tx freq due to doppler) ??

But that's sonar! I did something similar for a school project a long time ago... fun, but not radar. The only time I've done anything like amateur radio was when I was a friend's shack playing with their EME equipment. I did some clumsy morse, and a moment later it came back having bounced off some large lump of rock nearby.

This project resembles very much the "parking radars" you can get for
cars. They are really sonic and often operating at 40 kHz. You can get it
as a kit, look at:

http://www.elexp.com/kit_3502.htm
http://www.qkits.com/serv/qkits/velleman/pages/K3502.asp

HI,
I am very unhappy because my father gived me a digital volt/amp/ohm HP3465a
1982 's and the DMM coming out
in the power supply bord , on Q1(M739, motorola) , there is 8 volts on central
pin , and nothing on others
it seems to be a voltage regulator or an TO220 transistor like a darlington
TIP32 or other
is someone can tel me european equiv. for M752 and M739 or diagram of the DMM ?
is there an US/Europe table of these parts ?
i will be happy if someone can scan these table
73's
Serge

escuses me for appromative langage

french translation
Bonjour
suis bien ennuyï¿½ avec un ancien voltmetre digital de 1982 Sur un HP 3465a ,
l'appareil ne fonctionne plus , la basse tension s' arrete apres ces 2 betes
pourrait t il s'agir de regulateurs to220 ou darlington ou genre TIP32 ou
autres ?
sur le M752 , la pin centrale il arrive le 8 V mais rien n'en sort
Cordiales salutations
Serge

>superregens helped to pioneer the higher frequencies rather than
>the regen.

You'll see a lot of them in Handbooks of the 40's. They offered a lot for such a simple circuit. They have natural noise immunity, and very good sensitivity. The "rushing noise" of the squegging oscillator is soothing if you have the right kind of personality. Their biggest drawback was re-radiation, which could be solved by adding a broadly tuned preamp stage.

I think that Elecraft went with the LCDs that they chose for the K1 (and K2), rather than with character modules, because they could get bigger digits than the affordable modules offer. (The modules were also a lot more expensive a couple of years ago than they are now, so that may have been a factor.) Their approach may also use less power. The dot matrix modules are a lot more flexible, though, and the power consumption of the reflective versions isn't too bad.

As for the multiple microcontrollers, they are actually an elegant solution to the interconnect problem. If they didn't use a separate PIC on each board, they would have to run multiple control lines. With the PICs, they only need a single control line, simplifying the interboard connections considerably.

I have manual and it lists Q1 as a Motorola MJE2100. H/P part number
1854-0701. The Zener connect to it's base is a 5.23 volt .4 watt. Parts
are located on board A10A6 part number 03465-66506. Tom WB6IQD

You will need to generate some short duration pulses (a few milliseconds),
and then repeat them at a rate known as the pulse repatition frequency
(PRF). The range of the radar depends on this frequency, and also the rate
of the rotation of the scanner head (aerial), basically the lower the prf
and speed of rotation the greater the range.
Another crucial part is to switch the transmitter and receiver at a fairly
quick speed, pin diodes may be okay up to a few Ghz, or even better use a
circulator to isolate the Rx from the large Tx pulses, that way you could
leave the Rx running.
The PRF generator could be buffered to fire the timebase of an
oscilloscope...
Talking of scope, there is definately plenty of scope for experimentation,
dunno what the RA would make of it, but sounds like a fun project .

Best of luck.
Geoff (G8PPQ).

3237. earphones for crystal set

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-23 02:00:14 UTC
From: "Charles T. Young" <ctyoung@mtu.edu>
Message-ID: <tgm6de93blp093@corp.supernews.com>
Source record: 52584

So, I know how to build a crystal set. But, in the old days, we had magnetic earphones (nominally 2000 ohms). I still have a set. If I put those on a crystal set (with a good antenna and ground), I get LOTS of volume. I could probably drive a speaker if I could match impedances correctly. There are earphones that look a bit like this in the Antique Radio Supply catalog for about $20.

I have bought crystal sets with the stick-it-in-your-ear "crystal" earphones from Radio Shack and have bought "crystal" earphones from Antique Radio Supply. The volume available from these is PITIFUL compared to my ancient magnetic earphones. So the question comes up WHY?

Furthermore, I happened to be a judge at a science fair this year. This time, I saw a poor kid trying to make a crystal set with a pair of walkman type (low impedance) earphones. (Well, he followed the instructions in the old science book ...), But, you know its not going to work. You also know that the problem is impedance and sensitivity and that you are not going to be able to communicate that to the kid.

So, somewhere, somehow, someone has to know what we can do in the 21st century to help beginners make an honest crystal set. Maybe there is some adaptation we can do on those walkman earphones. An output transformer? I tried a little output transformer from Radio Shack and it didn't work. (Of course we know that we can make a one transistor impedance matcher/amplifier for the crystal set, but then that would be a crystal set anymore.)

The crystal set is such a nice lesson in basic radio. Four parts plus antenna and ground and you have a real radio. I hope we can find a solution.

If you have a solution, I would appreciate hearing about it via email, 'cause our newsgroup connection is so slow I don't use it much.

Thanks

Chuck

I use a pair of Deck Talker sound operated headphones
made by Dynalec. The impedance is only a 30 or
50 ohms, but the trick is using an extremely
high quality mike input transformer for matching.

You really need to check out the Crystal Set club
on Yahoo.

Go swamped grid, or passive as in my HT-33B, however I'd agree that the
regulation will most likely be poor. If I were going to use one of the
bigger 4CX series, I'd want a better power supply.

3247. Battery Charger for 12V 7AH Sealed Battery

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-23 06:54:52 UTC
From: Richard Schultz <roschult@jps.net>
Message-ID: <jcnmgtc0i4g2jjf6rpiopvd2cjpj3cc8oc@4ax.com>
Source record: 52594

Can anybody recommend a small trickle charger to charge and maintain 12V 7AH Sealed Battery? I just want to maintain a charge over long periods of time. The battery does not get used very much but when I want to use it once a month or so, I need it fully charged. Once the battery is drained I would want to charge it back up again and if it takes a full 2 days to recharge, that is ok.
Thanks in advance, Richard .

3248. meridian navigation box

Hi,
Does anyone have info on the Navigation Communication
Systems meridian satellite navigation hardware ... other trade name involved
is intech ... it is circa 1984 and has an 8085 micro processor board in in
connected to an amphenol connector backplane.

I believe the satellite system is now inactivated .. however the box has
a nice 16*2 lcd display , 16 key pad .. micro controller board and
a 5 MHx crystal oscillator .. all quite nice

I would like to use the micro and display/keypad and box to be the basis
of a receiver I wish to build ...

If anyone has info on the hardware or firmware please let me
know

Thanks

Stephen

> Best of luck.
> Geoff (G8PPQ).

Erm the pulses will have to be a few uSecs wide at the best. A pulsed magentron and a thyratron triggerd delay like is the classic way of producing a few kW (peak) of pulsed RF. I believe that IMPATT diodes can be pulsed and I know that transistor based radars are commonplace.

The receiver is isolated by things like TR cells, circulators and 1/4 wave lines, generally PIN diodes are too slow (but not in certain specialized systems).

Of course the range is defined by things like PRF, pulse width, antennae gain aand RCS. Get a copy of Skolnic.

Methinks that a good solution may be to digitise the azimuth and use a FFT processor on the IF and trigger from the PRF generator. Feed that lot into a good bit of software on a PC (NOT windows) and simulate a raster scanned PPI display.

Incidentally the UK amateur licence used to allow pulse mod with a mean input of 25W and 25kW peak pulse on bands above 23cms - I don't know if that is still valid.

3255. pc power supply use

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-23 20:59:44 UTC
From: caheaton@my-deja.com
Message-ID: <d0372cf9.0105231259.54465c91@posting.google.com>
Source record: 52451

Hello...recently here at work I had to ditch an "old" IBM 486SX pc into the dumpster. Being the good ham that I am, I first stripped it for parts. (Saved the drives, screws, cables, LED's, power supply, RAM, etc.) Last night I noticed that the rechargable lead acid battery (sealed) I use as my HT's 'base station' power supply no longer seems to be holding a charge. My idea is this...how suitable is an AT power supply for use as a ham power supply. I did a little research and supposedly these units are not good at providing stable power unless all voltage outputs are under load. Is this true? The power supply I have is rated (among its many ratings) 12V at 8 amps. This seems like it would be perfect for powering the HT. Anybody have any experience with this? I did put a volt meter on the supply while it was without any load (except for the exhaust fan built into the unit) and the meter read a little over 11 volts.

You need a 1488 and a 1489 to replace a MAX232.
You also need a +/- 15 volt source, AND a +5 volt source.
Less components, I don't think so.

The power supply you have salvaged is a switching type supply. It may be usable for supplying power but it may also be noisy.

A switching supply with multiple outputs usually uses only one of the secondary outputs to provide feedback to the PWM (Pulse width modulation) circuit. That particular secondary supply is the one that needs to be properly loaded in order for the feedback system to work as expected. The feedback is commonly provided by the secondary that provides the highest power (not necessarily voltage) for the system to which it is normally connected.

Hope this info might help you get the result you want from it.

And that would generally be the +5V supply to the mother board (the parallel-connected red wires on the motherboard connector(s). For the latest power supplies, this may be something less than 5V because of the requirements of modern CPU chips. (Can't run them at those 100s of MHz and GHz rates when you have to swing a full 5 volts!) VCC <1V is coming!

3262. UNBUILT Heathkit GR-104C 12” black and white portable television

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-24 02:48:50 UTC
From: yardleyite@aol.com
Message-ID: <20010523224850.15558.00001855@ng-fo1.aol.com>
Source record: 52458

On ebay: Item# 1240560126:
unbuilt Heathkit GR-104C 12” black and white portable television. It was originally purchased through a correspondence shool electronics course (please find a picture of the postmark of Sept. 27’76). It was opened once when new to inspect the upper layer of it’s contents, and then again by me to see if everything was there and to take a picture of it’s contents out of the box to show on ebay. I also have a picture from the manual of what it looks like when completed. All components appear to be in their unused excellent original condition, and free of mildew, etc. It was stored in a bedroom closet for the last 25 years to protect it from dampness, bugs, etc and it shows it. The original factory cartons appear a bit faded but are still intact and in good condition. The CRT was never removed from it’s carton and still has the plug protecting the pins at the end of it. . I obtained this item from a friend who explained to me that he never “got around” to putting it together. I don’t think I’ll ever get “aroundtuit” since I have many other projects to complete before I could ever get to it as well. It has all factory documentation, stickers, warranty card, manual (crisp and new) and a wonderful fold out schematic etc. It was explained to me that the CRT came in a separate box to avoid shipping damage. This would make an excellent project for anyone who ever wanted to build their own Heathkit television, or just keep as is for an investment. I have never seen an unbuilt Heathkit television before, and it is likely I will never see another one like this again. I have set a very modest reserve on it so bid up and enjoy the auction. You can purchase unbuilt Heathkit test equiptment, Radios etc. but you will rarely see a television. Thank you for reading about my item and the best of luck!

Hi Dick,

MAX233 has no external caps. Bigger DIP package, though, and costs a lot more than the newer version of the -232 and a few .1uF 50v ceramics.

1488's and 1489's are power hungry little beasties too. I quit using them a LONG time ago...

Have you downloaded the Maxim Interface chip datasheet?

In order to give them a long useful life , these sealed and other lead acid
batteries should not be discharged below approx 11.5 Volts .
If almost continuously in a fully charged state and used very little ,it is
advisable to discharge lead acid batteries to 11.5 VS. every three months.
Some time ago ,in response to a previous message on this NG , someone
reported that to keep the battery of his vintage car (used infrequently) in
a good condition ,he discharged it at regular intervals to 11.5 VS.

"Lars Brandt" <lov.brandt@telia.com> wrote ...
> This is only a test for see if I can attach an image on this server.

Mr. Brandt,
You have transgressed two major Usenet newsgroup rules:

1) NEVER (never, Never) post attachments, particularly binaries (pictures, documents, rich text, HTML, etc.) in a text-only newsgroup. It not only violates the charter, but also makes it difficult for people with text-only newsreaders, not to mention those who must pay by the minute for connectivity.

Furthermore, it jeopardizes the very existence of this newsgroup because many newsservers are not equipped with sufficient disk buffer size to handle large postings to what ought to be text-only newsgroups. News server administrators have been known to drop newsgroups that did not abide by the no-binaries charter.

2) AVOID posting "test" messges to regular newsgroups. Please use "test" newsgroups for testing your posting mechanism. There are literally dozens of them to choose from and nobody cares what you post to them.

If you wish to reference an image or other binary document, post it on the internet and provide a URL pointer to it. You have posted this image here twice now. Please stop. Following the rules makes it easier on everybody.

Hi All,

I was wondering if anyone here has modified a DJC1T for an external antenna?
If so which connector did you use? SMA?

Hi Craig!

I've used several single AT power supplies to power different projects.

The only time I;ve had a problem running off the 12v output is, on one supply, there is a "heart beat" that is only present during transmit. Receive is perfect.

If you use the 12v output of an AT power supply, ask for some signal quality reports to make sure you aren't introducing noise or "heart beats" into your transmissions. Also, if you're within range of a repeater which supports DVR (digital voice recorder, I believe) tests, you can tell the repeater to record the next transmission, which it then replays back to you. This feature of some repeaters can be invaluable when aiming directional antennas or troubleshooting radios!

Using a different supply solved my heart beat issue, so not all AT power supplies are alike.

If you're in need of a power supply which is more stable and more power, check out:
http://www.antennex.com/preview/archive3/powers.htm

This article by August Hoecker, W8MIA, describes how to use the +5v outputs from several AT type PC power supplies to build a quite functional power supply.

I've built one of these using 3 power supplies rated 5v @ 20amp and can pull about 22-24amps before the supplies shut down.

One major advantage to this setup instead of using the +12v of the PC PSU is that the +12v drops significantly under high loads. My supplies drop to about 10.8-11v when I approach the amp limit of the 12v output. By wiring the supplies in series and fiddling with the 5v regulator pot, under zero load the supply outputs 14.2v and under a small load (less than 2amps) the voltage drops to 13.9v and stays there under all loads up to the 22-24amp upper limit.

As the article will tell you, BE CAREFUL! There are very high voltages in these supplies and you must be careful modifying the supplies to work in series!

August was excellent in answering all of my questions and loves to hear of success stories!

Here is another article:
http://www.procooling.com/articles/html/on_da_edge_of_psu_technology.shtml

This one references August's article and goes into further detail in a couple places.

Keep in mind, this supply is flexible! With my 3 supplies, I have outputs for +5v, +9.5v, and +13.9v outputs (by tapping between the supplies) rated at about 20amps as well!

I hope this helps! Let me know if you have any questions (reply via e-mail).

Good luck and 73,

-Rich

Many non-binary news servers will reject a photo attachment, on either
or both the receiving or transmitting side. Its a question of saving
storage space. Your one photo may cause 50 or so text posts to expire
prematurely. As a result, its considered bad practice to post them.
You can use alt.binaries.pictures.radio

3272. Microcontroller advice?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-24 13:35:28 UTC
From: w9wi@linux1.localdomain
Message-ID: <slrn9gq0dq.9op.w9wi@linux1.localdomain>
Source record: 52466

I'm working on an antenna-switching project. Had hoped to use a Basic Stamp, but I forgot to read the specs before starting - and found the Stamps don't have nearly enough I/O.. so I'm looking for suggestions on other devices/boards..

I need at least 10 digital inputs and at least 10 digital outputs. (12 of each would be real nice. No analog or serial I/O necessary.) I've never worked with microcontrollers before, so something with flash or some other form of reprogrammable program memory is important. External EPROMs will do. (the chances I'll get the software right on the first try are essentially zero!) Needs to be reasonably priced - $150 or less for the controller and any "glue"/monitor ROMs/etc. Size, speed, and power consumption are not important. (I have even considered using a PC with ISA I/O cards though the I/O cards seem to fail the price criteria)

Suggestions anyone? Thanks!

PIC 16F877 has 40 pins, 33 i/o ports, built in UART, 8K Flash program storage, lots of register RAM. Do-all-be-all piece of silicon wizardry.

Development kit can be as cheap as FREE (MPLAB/ASM available on website) if you homebrew a programmer, but their ICD is about $150 which will program any of the 87x parts plus give a nice little platform to test circuits. Chip is available in stock from Digikey. You can also get various flavors of C and BASIC if you're not an assembly language fanatic.

http://www.microchip.com

You can also increase the number of ports on a Stamp with some latches. I did a 16 x 16 (yes, 16 receivers looking at 16 antennas, any receiver with any antenna) antenna switching matrix project a few years ago with some HCT 16 port latches, optoisolators, a PIC 16C84, and about 2000 bucks worth of hybrid splitters and MMICs from MCL.

Doug,

You might want to look at the Atmel AVR series. You can get the entire development system for about $80. See http://www.atmel.com/atmel/ad/mcu_order.html for information.

I use Microchip PICs with CCS C compiler and love that environment, but
you would have to learn how to do all this and get a programmer.

I haven't used the Stamp but I'm thinking, one possibility is to use the
stamp and add external shift registers for the input and output lines
you need. The stamp would use 3 lines (clock, data, enable) and the
clock and data lines can be shared between both in and out chips. I
have done this with smaller PICs to get more I/O. Its a little slower
than dedicated inputs and outputs, but probably not important in most
apps.

Most RS-232 interface chips have on chip switchers generating the
required +/-12 V lines. Why couldn't we have super fast processors
with on-chip switching regulators generating 0.86 V from +5 V or +12
V, thus avoiding the huge currents required :-). With high enough
switching frequency, the inductors and/or capacitors would not have to
be very large.

You need to find out how the wires are connected, either by getting hold of the data for the motor, or with an ohm-meter. You can then connect driver transistors to the coils (don't forget diodes to protect the transistors), and devise a circuit to apply the correct pulse sequence. A PC printer port and some simple software will do for testing., and a microcontroller is ideal for the final version.

Take a look at http://covingtoninnovations.com/noppp/index.html for a 16F84 programmer. The 16F84 doesn't have enough I/O for your tastes, but building it for another PIC is as simple as changing the socket. Yeah, you would need to read the spec sheet (http://www.microchip.com/10/lit/pline/picmicro/families/16f87x/index.htm) to figure out which pins to hook up.

This programmer is built from stuff you must have in the junk box. If you have absolutely no junk box, I calculated the parts at $7 at Radio Shack prices! OK, OK, a little more if you fancy it up with a nice ZIF socket.

Rummage through DigiKey's catalog (http://info.digikey.com/T012/V4/200-211.pdf) ... there are a ton of different PICs, all the 16F ones program the same, but there are all sorts of variations on number of I/O's, A/D's, prescalers, timers, etc.

As Rory points out, the development environment is free, (http://www.microchip.com/10/tools/index.htm) the price of the PIC varies with the capability but the sort you're looking for is likely around ten bucks.

I personally use PICs - they have a large following. Another possibility
are the AVR series. Check around locally and see if anyone is into
microcontrollers and if you find someone willing to help use what they
do.

If you are going to expand using shift regs look at the 74HC595 and
74HC597 - they have built in latches so you can get all the bits to
change at the same time.

Of course, you COULD use a "cheap and dirty" approach. A PC can use
the parallel port with some latching to give you all the I/O pins you want
plus more.

Yeah, I know, a big and clunky way to go but it could be used as part of
a more sophisticated program control for the entire station.

I have built versions of this over the years for several applications and
found it a simple way to gather data from ATE gear and then number crunch it
on the spot, so to speak.

The good part is, it's MIGHTY cheap if you have an old PC around and for
a one-off solution is probably the simplest to get operating.

3288. Pll question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-25 17:55:40 UTC
From: jimbo@unknown.demon.co.uk
Message-ID: <3b0e9a28.40682005@news.demon.co.uk>
Source record: 52485

I am In the process of building a pll board for the vhf region. The thing doesnt work basically, and i have put it down to the dividing chip,(but i know these do work at this frequency) Im using a 74hc4024 to divide around 90megs to half. This then feeds a 4059 divide by n counter. The problem seems to be that the output of the 4024 is not strong enough to drive the 4059, but, if you choose one of the outputs of around say 5 meg from the counter, the wave looks fine and drives the 4059. It just doesnt want to drive it with the output at half frequency, or half that. Wonder if anyone has any ideas on the matter ?

Is it anything to do with the coupling from the oscillator to the 4024? I couldnt get a value of the cap from the pll i copied so i just used a 27 p. Anyone have any ideas there ?

Would it be advisable to chop all the legs off from those remaining on the 4024 ?

Any help would be appreciated.

Jimbo

Right off you have two problems. The first is that according to the databook, the 74HC4024 is only good to a clocking frequency of 32MHz at best (and the lower the supply voltage, the lower the top frequency goes).

The second is that if you are using it to divide a 90MHz frequency by two, the device that is following it has to be able to clock at that frequency, ie 45MHz. Since you only say it's a "4059" we must assume that it's just the regular 4000 series of CMOS. And that will only clock at a maximum of a few MHz. Again, the lower the supply voltage, the lower the maximum clock frequency. If the thing works when you use the 4024 to divide by more than 2, what is happening is that you are getting your input frequency of 90Mhz down to a range where the 4059 can work.

Go back and read the theory books. YOu're clutching at ideas, "the output isn't strong enough" and "should I cut off the extra pins" rather than understand the basics.

The whole point of a fixed divider ahead of the programmable
divider is to get the frequency down to a range where the latter
will clock properly. If you had a programmable divider that
ran fine at 90MHz, there would be no need for the prescaler.

YOu need a strong enough signal into the prescaler, though you
don't want to load the oscillator. IN some cases, you may need
to buffer the oscillator signal and maybe use some circuit
to square it up for the counter. Then you need a counter that
will operate properly at the input frequency. Throw out the
CMOS, and use a logic family appropriate at that frequency,
I can never remember all the combinations, but it will be something
lie teh AS series. You won't find a "4024" in the proper family,
so you'll have to go to something like a flip-flop of some kind,
set up to divide by two.

Then, you either need to move to a programmable divider that will
clock at 45MHz, methinks at that range you'll have to make it
up with a number of programmable decade counters. Or cascade
some other flip-flops after the first one to get the frequency
down to the needed range for the 4059.

Note that the fixed divider ahead of the 4059 will affect the
operation of the rest of the circuit. The steps of the PLL (ie
the channel spacing) will be the reference frequency multiplied
by the fixed divider rate. So say you have a PLL reference
frequency of 1KHz. If the fixed divider between the oscillator
and the 4059 is 2, then the steps will be 2KHz. If the fixed
divider is 4, the steps will be 4KHz. 90Mhz divided by 16
gets you to a frequency just under 6MHz, so your steps with
that divisor will be 16KHz apart.

Just had a look at the circuit diagram for the vco. It appears (i think) it follows a doubling circuit so i should have tuned it down to half the freqwuency. Sound a bit more like it ?

Don't think I'll do anything as complicated as that, but I have some ideas
for using an oscilloscope as the display. One is to feed the X and Y inputs
with sine-cosine waves, (a cosine wave is a sine wave of the same frequency
but phase-shifted by 90 deg.), this should result in a circular sweep, then
if you amplitude modulate both with a sawtooth at PRF you should get a PPI
(plan position indicator, the usual kind of radar display), Z-modulation
(trace brightness) indicating targets.

I went out to a site recently with a friend who is a paging tech, and the receiver he was working on puzzled me a bit. Apparently this receiver is for 901.25625 MHz (seems a bit odd to me), it uses 2 antennas, and he couldn't check sensitivity.. only noise levels?! When he checked it, he had -174 dBm/Hz on one antenna, and -144 dBm/Hz on the other antenna.

When he initially tried to check the readings, they wouldn't read out until some data came through the receiver.

Can someone please explain how this all relates to sensitivity? Is there a way to tell how sensitive the receiver is from the noise readings? He told me that one antenna was quiet, and one was noisy?

Any help or pointers would be appreciated.

Shawn

Yes, a magnetic scan version of this was indeed done in "static coil"
displays before raster scan systems became practical (memory arrays etc),
but unless you have a P7 type phosphor, the PPI on a scope display will
hardly be readable. The asimuth info was derived by the use of 360 deg
rotation sine/cosine pots and used to control variable gain X and Y
amplifiers that were fed via an "A scan" ramp.

>on the other antenna.

In white noise, there is always the same amount of noise power in a
specific bandwidth regardless at which absolute frequency it is
measured, thus the noise density is the same. The notation -174 dBm/Hz
means that when using a 1 Hz measuring bandwidth, the noise power is
-174 dB below 1 mW.

Thus, if your receiver bandwidth would be 10 Hz, the noise power would
be 10 times (+10 dB) stronger, thus the total noise power would be
-164 dBm.

Assuming a SSB receiver with 3 kHz bandwidth, the total noise power
would be 3000 times (about +35 dB) stronger than at 1 Hz, thus, the
total noise power at the receiver input (including the noise generated
by the receiver) would be -139 dBm.

By the way, the -174 dBm/Hz noise corresponds to a 300 K noise
temperature and since the average temperature on earth is just below
300 K, so you will typically get this amount of noise in the UHF and
microwave bands, when you point your antenna to any terrestrial
object. Lower noise temperatures can be obtained by pointing the
antenna to an "empty" region in the sky, but the final limit is the
cosmic 3 K background radiation from all directions (at about -195
dBm/Hz noise density).

>Can someone please explain how this all relates to sensitivity?

In order to be able to transfer some true information (something that
was not known before), the signal must be stronger than noise (in
spread spectrum systems, this must be measured after despreading). In
order to be able to reliably extract the information, the signal must
in practical system often be several times stronger than the noise,
for SSB we are usually talking about levels at least 10 dB stronger
than noise. Thus, if the receiver had a noise level of -139 dBm, the
signal would have to be -129 dBm to get a 10 dB SNR. This is the
sensitivity of the receiver. This can then be converted to microvolts
when you know the impedance level (typically 50 or 75 ohms). For a 50

ohm system, that is about 0.08 ï¿½V.

The sensitivity can be calculated from

P = ND + 10log(BW) + SNR

in which P is the receiver sensitivity in dBm, ND is noise density in dBm/Hz, BW is the receiver bandwidth in Hz and the required SNR is in dB.

I agree -- almost everyone has a Windows 3.01 laptop lying around somewhere. I have a Toshiba '486 which I use in DOS, and for data logging, control and and experimentation it's excellent in what I guess you would call it's "native mode".

You might suggest "Parallel Port Complete" or "Serial Port Complete". two readily available books which explain with schematics and code how to get it done.

A bit off topic for this NG. There is a good selection
of free, shareware and commercial satellite tracking
programs. I use SatTrack and Predict for Linux.

Have a look at www.amsat.org

_/

"I'm sure you've noticed the RAPID decline in the AVAILABILITY
of certain DUAL-IN-LINE COMPONENTS.

The devices MIGHT still be available but ONLY in their SURFACE
MOUNT form.

So how DO YOU construct PCBs using these TINY devices?

To enable you to KEEP UP with the TECHNOLOGY, I've created a
FREE EMAIL COURSE that contains a series of special techniques
to address these problems.

The course uses techniques that ONLY require LOW COST HAND TOOLS
and is mainly intended for PROTOTYPE PCB DESIGNS.

The course consists of ONE EMAIL EVERY DAY covering the following
topics:-

* Working Practices
* Good and Bad Joints
* Soldering Rules
* SMT Pads
* VIA Holes
* IC Sockets
* SMT Components
* Solder Levelling
* Fine Pitch SMTs
* Handling SMTs
* Removing SMTs
* PCB Example
* FAQs
* Course Summary

To ENROL on the course please EMAIL:-

PCB-Course@biz-e-bot.com

with the word SUBSCRIBE inserted in the SUBJECT LINE.

"Throughout the course there is FEEDBACK available to answer
ANY of your questions and the option to TERMINATE the course
at ANYTIME."

This may be a little off the beaten track; I am not sure if you are copying a design or not. At the last place that I was working, we used to use the 74AC family of chips. They are current hogs, but they provide the fast edge rates to the phase detector that are important for keeping the phase noise of the synthesizer down.

I thought about playing with pulse radar on the amateur bands about 10 years back, inspired by an article in Sept or Oct 1983 of Ham Radio Magazine, about constructing a WX radar on 3cm band using a gunnplexor. It wasn't really pulsed but was chirped! Question of course was the legality and also the article seemed to be incomplete. I never completed it.
Then I was talking to some other amateur at the time who was knowledgeable about radar and his recomendation was to try a boat radar which of course is legal to use in the marine bands, forget about the amateur bands. These use magnatrons operating around 9.4 ghz with peak powers ranging from maybe 2kw to much higher. I did some experimenting and found that with a 3kw unit it could detect thunderstorms out to 20 km or more. Pretty neat! As far as legality, I am not a lawyer but I believe in the U.S. that there is no license requirement for operating these so long as you don't try to repair one. Then it requires a commercial license.
On the otherhand be careful and don't put your eyes to near the antenna or especially if it is not rotating. Worst of all the peering into the open waveguide as the energy comes right out from the magnitron.
Hope this Helps,
Vince Coppola

Thanks for the advice all, i did manage to get the thing working today
after hours of frustration and testing. The 74hc4024 manages to
cope with 45 megs, the oscillator is on f / 2, but the signal coming
out of the 4059 into the pll
is very weak. I found out by looking on a scope the reason for the
diode and cap on the input to the pll. Seems to make the signal a bit
more square like, it was these that i didnt put in that made the thing
not work, and the frequency being too high also.

cheers

Jimbo

For reference, marine radar requires licencing in the UK. Not particularly
onerous, you fill in a form, pay 20GBP to SSL and switch on. Oh, and you
have to operate it from a boat!

> On the otherhand be careful and don't put your eyes to near the antenna or

That can guarantee blindness. I was taught many years back that the only way
you EVER look into a length of waveguide is after you have put your
hand/finger/whatever (waveguide comes in a wide range of sizes!) in the
other end. The output power of a gunn or klystron local oscillator can cause
damage, the output of a magnetron WILL cause damage to your eyes or other
parts (think of a microwave oven).

PLL circuits are not for ther faint hearted and the design of the loop filter will be a problem. You cannot use CMOS logic at the frequencies you are talking about. There are lots of app notes at various manufacturer's websites on PLL circuits. I have some articles on the topic and I have a design for a generic PLL board to work at 50 MHz, though it could be used at other frequencies.
See http://www.iinet.net.au/~richardh/VK6BRO.htm

There's nothing special about that modulator, and it's the sort of
circuit that has shown up plenty of times before. Note that he
doesn't even bother using fancy diodes, but simply specifies

"1N914's".

Actually, just to see if the circuit was correct, I went looking and while simple two-diode balanced modulators are common, this one isn't quite. You see it in reverse, ie the signal comes off the toroid transformer and the oscillator feeds the pot, and you see other variations of the same basic parts. Without digging through magazines, the only similar circuit I found was in Doug's W1FB's Design Notebook, where he shows a similar circuit, but no pot.

It can't be the circuit. I assume you've checked the circuit to make sure the toroid is wired right and the diodes are properly in place.

Try putting some voltage, current limited, at the junction of R9 and the transformer. That should unbalance things and give you a strong output. If not, the thing must not be working. Maybe you've got a false null, that for some reason the pot isn't balancing things, but just reducing output.

Anyone have a simple schematic for an amplifier to increase the audio in the handset of a telephone receiver.Should be powered via the receive audio.
Tnx, AA8X Bob

3319. Modulator Problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-27 18:02:49 UTC
From: n2cqr@clix.pt
Message-ID: <3b1140a8.24413723@news.clix.pt>
Source record: 52413

I made my first QSO with the 17 meter DSB rig, but it was more of a test than a QSO: after much fruitless calling I was forced to resort to a sked. CU2BD pointed his beam at me from the other side of Ponta Delgada (3km)...and still had trouble hearing me. He said the audio sounded OK, but very weak.

The problem is low output in the DSB mode. I think I've localized the trouble to the Balanced Modulator. This is a simple transformer/two diode circuit. It appears on Page 139 of W1FB's QRP Notebook.

I am able to 'balance out' the RF. When I unbalance the modulator (using the balance pot), I get about 1 watt out of the final (this is about right). But when I once again balance out the carrier and try to modulate, I can barely make the SWR/Output meter wiggle. Even when whistling, I can barely get the meter to move. I am modulating the signal, but just not enough.

I don't think the problem is insufficient audio. My audio amplifier (a 741 op amp) is working fine. And I tried injecting a 1 khz tone (at about 1 volt rms) into the AF port of the balance modulator -- no joy. I put the same signal into the input of the Op amp. Again, no luck.

So it is as if half of the balanced modulator (the RF half) is working fine (I can null out the carrier) but the audio portion seems unable to "unbalance" the modulator properly. I think the audio should be able to produce a level of "unbalancing" similar to what happens when I turn the balance pot to either end, but so far it is not even close.

I'm using two Motorola IN5821977 Hot carrier diodes. The both show forward resistance of about 5 ohms. (This is what I had in the junk box -- do you guys think this is a suitable component?)

I'm stumped. Anyone have any ideas on what's wrong or how I should proceed?

There is no substitute for looking at the circuit with an oscilloscope. Make sure the output of the amplifier is substantial; if it's not working the modulator won't work either. Check the output of the amplifier and see that it's giving you the gain you expect and that it isn't distorting the signal.

Greetings! At the frequency that you are operating (90Mhz), I use in one of my designs a prescaler (divide by 2) made by NEC/CEL number UPB1509GV because it will run on sinewaves from the VCO at 50 Mhz and upper. The pre-scaler also can devide by 4 and 8 and is well compatible with the Motorola MC145151P2 PLL. Using the IC's that you mention, may require a "SQUARER" between the VCO and the divider by 2 which may be done by a schmitt trigger if you can find one that will work at 90 Mhz. The VCO output level must also be capable of triggering the squarer. The UPB1509 will work with -20 DBM at the input at 90 Mhz. VE2AUC

Michael: I put 2 volts at the junction of R9 and the transformer. I got some small increase in output, but not much. It was sort of similar to the levels I get with the microphone -- I can see the output meter moving, but it is not swinging up to anywhere near the 1 watt level I get when I unbalance the modulator.

A guy who's worked with these circuits e-mailed me saying that modulated output from this type of balanced modularot SHOULD be about 10db below the level you get when you unbalance the circuit. If that is correct, my device is performing to specs! (But I can't believe W1FB woulldn't have mentioned this and designed for it -- I'm using both his DSSC generator circuit and the RF amp that he designed to go with it. And he said it would yield 1 watt PEP.)

I'm now thinking that one more stage of RF amplification might bring me up to the 1 watt level. I am getting some generation of a Double Sideband sig -- just not enough. What do you think of an additional stage of RF AMP?

If you like programming in assembly language, (I do, because then I know exactly what I'm doing), the Atmel series of microcontrollers is superb. (Of course, there are also efficient C-compilers available). The chip can be reprogrammed on board after it is soldered in place. You get free assembler and simulator from Atmel, and a free programmer using the parallel port on the PC (software by Jerry Meng http://www.qsl.net/ba1fb). One drawback, however, if you have Windows 2000 or NT the programmer will not work (in that case you are not allowed to write directly to the printer port).

Some years back there were special "Hard of hearing handsets' (some had a volume control built in) for the then conventional type 500, type 2500 etc. Bell System phones. IIRC they were powered by the DC sent out from the telephone exchange to provide signalling and to energiize the transmiiter (microphone) in the telephone handset. A typical loop current would have been between 30 and 80 milliamps. The carbon granule microphone and later the electret microphone only required a volt or two to operate.
Suggest you might try a telecomm news group, but chances are there are some "Telephone Industry (maybe even Telephone Pioneers)", here who could comment?
Hold on a mo. I've got an old subscriber equipment Bell System I and R handbook somewhere ....
Telephone set 532B containing a 151B amplifier (has adjustable gain) described as "Amplifier set for impaired hearing". There is only a general diagram of the single transistor 151B amp.
Many later telephone sets have either a slide switch volume control or slide potentiometer with an amplifier built into the telphone 'network' that is within each phone. AFIK all of these need/use the DC energization from the telephone exchange. Since only a few milliamps would probably be required maybe it could be got from the DC supply of a radio receiver? And perhaps you could use one of these out of a phone?
Terry.

We ordered amplified Bell handsets for our older
4-wire digital phones at work. The amplifier was
in the handset, and there was a small sideways
pot to set the volume.

This is also true of the MicroChip parts, however there are some constraints on your circuit, and I suspect that's also the case with Atmel.

I think you are going to find that to be the case for most of the programmers at least as far as Win2K is concerned. Many have resolved the issue with NT but on either NT or Win2K it's pretty tough sledding and not enough folks are using Win2K yet to make it worth the effort. Certainly the cheap/free programmers this will be the case.

One trick which may work if you have computer control software for it, is
entering the frequency desired in with said software. There is the freeware
software from Russia, as well as the ADMS software (which isn't freeware) which
might work. I remember typing in several frequencies which didn't quite match
normal steps, and having them show up until I "corrected" them. You do of
course need an interface, but once again it is possible to homebrew one cheaply
rather than using the one associated with ADMS. I'm not sure if the
frequencies entered that way would actually work, I just noted what were to me
oddball frequencies that I had entered, apparently in a state of previously
unknown dyslexia, and showed up on the display as such.

There are some PIC programmers on the market which do use LPT: under NT4.0. ePIC / MicroEngineering Labs ~ $60 distributed by Jameco etc. I do my professional development using one of these and it works just fine - and faster than the programmer from Microchip.

For the PIC16F87x series, you need a 2x5 0.1" header and you can use the ePIC to program in-circuit.

I have used the Mot. 68HCxx series for years and the PIC with a decent C compiler blows the Mot. out of the water for $ / bang (or is it bang per $?).

Mark.

3340. Re: Home Brew Rotator????

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-28 15:15:54 UTC
From: Bill Cromwell <bcromwell1@earthlink.net>
Message-ID: <KYtQ6.42279$9D5.2558571@newsread2.prod.itd.earthlink.net>
Source record: 52434

I once saw an article about a homebrew hydraulic antenna rotator. The rotating shaft had a pin that rode in a spiral slot. When the operator pumped up the hydraulic system the rotating shaft rose forcing the it to turn at the same time because of the pin in the spiral slot. Opening a release valve a bit allowed the rotating shaft to lower again of its own weight turning it back the other way.

The hydraulic system was from an old automotive jack as I remember. The hydraulic system was the same. Pump it up to turn one way. Release oil back to the reservoir to go back the other way. This one did not generate any electrical noise and it worked even in rolling blackouts.

The Atmel RISC chips are 4 times faster than microchips version as the Atmel chips are mostly single cycle execution times where as microchip devices (PIC's) are 4-cycle.

Depends what speed you want out of the chip really.

The rotating part is the easy one. You could even use bearing plates and clamps to hold the mast up while you turned the other end from the bottom of the tower (remember to include a locking system too). Aiming it would be the fun part. Unless you use visual to aim the antenna and maybe a compass, you'll need a feedback system to show you where it's at if you have a remote system.

You can't find an old tv rotor around cheap at a junk shop or yard sale. Maybe try an ad in the local paper for one?

There's also the old "Armstrong" rotator; the name says it all.

I worked on RF hardware and software design of spread spectrum phones. The US government would have a serverly hard time decoding a spread spectrum signal phone (its easier to just tap the line...hehehe). The base unit passes the handset a "seed" this seed corresponds to a psuedo-random high speed code on which the multichipped audio stream is EX-OR'ed with. Also there are control signals passed back and forth between base and handset....not to mention channel selection...etc. Sounds complicated yet?.....well there is more.....Your receiver archetecture only takes care of the physical radio demodulation......there is the software layer that is the BIG unknown, that layer takes care of EVERYTHING, if you have no clue how or what it does you will be spinning your wheels for years.

I recently picked up a used Ramsey VHF FM transceiver (already built
from a kit) at Dayton.
These radios are synthesized but limited to 12 channels through a rotary
switch and diode programming matrices.

I seem to recall a magazine article some years ago on interfacing BCD
thumbwheel switches to the rig for frequency agility.
Can anyone recall the article date or send me a copy of the article ?

(NOTE: I'm not interested in the pc interface...I need it to be
portable and not tied into a computer.)

Source record: 52444

Hmmm.... As I recall, the actual programming is a binary code.
Probably the "best" by way of being relatively simple to build and fit in the ramsey radio would be a prom. The thing to do is to program it so the input address is BCD and the output is the actual binary.

Seems to me there is a need to set the program on frequency while Tx and add an offset while Rx to allow for the Rx intermediate frequency.

You could allow for that as well, by using one of the input address lines as the Tx/Rx select.
And, of course, two more lines to allow for the simplex/duplex offsets.

All this will require a fair amount of fooling around to sort out the actual data to put in the prom, but it IS possible and a fairly simple solution once the code has been sorted out.

Oh yeah, you should include one of the output data lines as a "TX Enable" which would enable the Tx only when programmed for a legal ham frequency. Otherwise you might wind up transmitting out of band since this system could be set up to allow tuning across the public service frequencies.

You could, of course, make a dedicated prom, set for the local frequencies of interest and then use a simple up-down button to feed a counter and a display to show the frequency. Kinda depends on how complex you want to make it all

==========

Otherwise, I think it'd take a PIC or something similar to compute the conversion "on the go" which means figuring out the program to do it, programming the pic, and installing it.

The PIC is perhaps a more elegant solution, since you could add pushbutton entry and an LCD display. Otherwise, you'd have to add a method of scanning the thumbwheels....

I think there was an article in 73 about this, but since mine aren't in any sense of order, I can't easily search for it. I'm pretty sure they used a switch between the BCD switches and the board for the diode matrix.

Significantly, all of this had been done years before, with the ICom IC-22S. It had 22 position switch, but like the Ramsey one programmed the specific frequencies by diodes on a board. It seemed like almost as soon as the rig hit the market, there were articles about easily making it tune all the frequencies. There was a wide variety of solutions, and probably most if not all would translate to the Ramsey.

The simplest solution is to go with DIP switches. INstead of hardwiring diodes each time you need a new frequency, the switches emulate the diodes. You'd need a lookup table handy, just as you would when changing diodes. But it is simple and cheap.

Rotary switches are more convenient. I've found switches that had 16 positions that put out some kind of digital output. Right at the moment, I can't remember what code they put out, but there were four outputs. Again, have a chart handy to do the conversion.

With lots of help and advice from list members, I got the modulator working
on my homebrew 17 meter DSB rig. I checked and re-checked everything and
finally decided to pull out the Schottky diodes I had in there and try some
ordinary diodes. (I don't even know the designation for the new ones -- I
picked them up at a Radio Shack a long time ago and they have been lurking
in my junk box ever since.)

BINGO! With the new diodes I was able to null out the carrier and get
approximately 1 Watt PEP our of the rig. I'm sure the audio doesn't sound
great, but I can work on that later. For now, I'm very happy to see the
power output/SWR meter bouncing nicely as I call (futile!) CQ's!

I don't know why the other diode's didn't work. They tested fine, with high
reverse and low forward resistance.

Thanks again to all those who helped. I will continue to keep you posted
on progress (and I will probably be asking for more help on future
problems).

I think I'll be building another RF amp stage to get me up to 5-10 watts or
so. Then it will be on to the companion Direct Conversion Receiver. This
is, after all, a Direct Conversion transmitter!

Cross-posted to: sci.electronics.equipment,sci.electronics.misc,rec.audio.marketplace,rec.audio.tech,rec.radio.amateur.equipment, rec.radio.amateur.homebrew,rec.radio.amateur.swap

There used to be a mini FM transmitter made by Selectronics called the "Sound Bridge" model SB100.

I would like to know if anyone might have any contact information from that company or the company from whom these units may have been obtained?

At one point in time, they were sold by All Electronics and by Parts-Express. I have written to both of these companies with no luck.

At some point in time, these units were also given away free to customers ordering a certain CD player or players. If that rings a bell with anyone who might remember which company offered them as a free bonus, that might help me track them down.

I'm looking to either order some in quantity, find a company who made them or distributed them, or find a schematic.

You can see a photo of the SB100 at:
http://mem.tcon.net/users/5010/5491/sb100.gif

AmDX-

Alas, no load so no brute force answer.

Meter reads to 0.1 Ohm.

Measuring windings R
Secondary reads zero so worst case is less than 0.05 Ohm
Primary reads 0.6 Ohm

My math says WORST 30A will be 12.5 Volts.

-t

In old days of Usenet it was considered bad form
not to CC the poster via email when replying to the
group.

I recently was donated a bunch of Marconi DP93 VHF HT radios. These radios are 16ch and have a TNC antenna connector not a BNC. I was wondering if anyone could tell me if it is possible to convert these to 2M, and if so how? There was also a FTC-2205 HT that I would like to convert. I also acquired a Century II mobile 25W VHF radio that I was wondering the same about. It is very similar to the GE Phoenix SX but a little different inside. I am planning on selling these for a club fund raiser. If you have any info on these radios please let me know. Thanks.

I just noticed the cross posting to everybody@everywhere and removed all but "my" group.

I suspected that trying to monitor spread spectrum would not be practical and might only be a possibility with your own equipment. You would have the "keys" to your own equipment. Something along the line of a one-way intercom.

I bought some of those cheap intercom sets that use the homestead power wiring to communicate. Works fine... no hassles, no aggravation. One each in the kitchen, the parlor, the basement, and the barn. I suppose those could be homebrewed, too.

Hear! Hear!

Nortex is amazing - the classic Surplus Electronic Junk Store.
An endangered species, alas...

Go there. Spend lots of money. It's not difficult. :-)

I also spent quite a bit at Tanner's my last trip to DFW.
I don't see Tanner's and Nortex as competition: they sell
different things.

You probably paid too much at Radio Shack and thats why they're touchy about electrical noise. I bought el-cheapo units at Office Depot. They aren't sensitive enough to receive line noises <grin>

3376. Antenna T-match Network Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-05-31 13:27:21 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9f5h82$1lq$5@uranium.btinternet.com>
Source record: 52373

NEW PROGRAM " T_TUNER.exe "

This program assists with selecting maximum component values
necessary to secure an impedance match when confronted with a
specified wide range of feeder or antenna input impedances.

For given coil and capacitor Q's, and power input, the power
dissipated and lost in each component is calculated. Also all
currents and voltages.

Input and ouput image impedances are calculated. The program will
demonstrate that the output image impedance is the conjugate of the
feedline input imedance. By first of all setting Q values to
infinity, it will also demonstrate that when a conjugate match
exists at one end of a network a conjugate match will exist at the
other end only when the network is lossless. Or conversely, if a
conjugate match exists at one end of a lossy network, a conjugate
match cannot exist at the other end.

51 kilobytes. One file only. Not zipped up. Download program
T_MATCH in a few seconds. Run immediately.

John: Thanks for your comments. I wish I had this info before I ordered the parts for making one myself. Believe it or not, the connectors are still being made and are sold by Mouser, should anyone else need them. I have had several emails that contain the info that I needed to build one, including one that pointed out that the tracking generator is not compatible with my 8553L rf section. Win some and lose some.
thanks again.

That's probably a safe approach, although not all the pins will need to
be connected. Talk to George Kerber at glkinst@earthlink.net; he makes
a lot of these cables for people and will probably be glad to advise you
on the pinout.

Could someone recommend a good FM Transmitter for MP3 playaround house. I would like 12 v and 120v capability, Stereo, and appx 1/4 mile range. Had a Canakit, but destroyed it trying to set it up in a case with switching for voltages so would like something already built and in a case. Am in US and would like it to be in $100 or about range.
Any suggestions?

Thanks,
John

your house is 1/4 mile long?

> Any suggestions?

Still not sure if you want a 1/4 mile pirate transmitter, or a "just around the house" repeater like you first mentioned. These are two completely different items.

My station runs off solar / battery power, so I don't want to waste electricity needed for the transmitter. My plan is to fashion a manually cranked rotator, made from a discarded garage door opener. It is gear-reduced 3 times, with the final drive shaft intended to turn the entire mast from the bottom end.
A compass rose marked on the tower base will indicate the direction of the beam. The crank is going to be bolted onto the motor drive pulley. Best of all, it is practically cost free. 73 JJ

Reason I say 1/4 mile is that we have some dock parties at a Marina and thought it would be great to be able to transmit around the marina for those. Also, Canakit was a bit weak while it worked throughout the house, it was not a great signal.

Perhaps you could recommend a couple different types, a home and a pirate transmitter?

John,

I'm pretty sure you can adapt the older RF sections for use with the 8443A, I've done it, but without the 3 appropriate manuals you will be lost; up the proverbial creek....

As far as I can remember, it is "simply" a question of bringing the 3MHz IF from the 8552, thru the RF/IF interconnect, to the connector (you'll have to get the insert) at the rear of the RF unit. If your unit has any of the inserts A2 thru A7 missing at the 8 way D-sub combo connector; that is what you will need to get. If you have a really old 141T it may also be lacking that connection to the outside world....

Dan

Here's a good website to purchase a FM Transmitter. It's in the UK but they ship all around the world and the distance these transmitters cover are huge and in stereo at a very cheap price. I'm 14 and I've got a 1 mile stero transmitter for about £35 ($70).

Here's the address.

Hasn't anybody heard of CW radar? Better still what aboput PRN
modulated radar. The process gain can be made quite large and
therefore the radiated power can be quite moderate. Get with the
STRENGTH.

With a bit of clever programming one could convert a PPI display to be
stored digitally on a PC or other computer/micro. This would get over
the P7 phosphor problem.

The Veronica one watt pl unit listed here is more than enough to cover your
Marina and then some.
http://www.ldbrewer.com/lpfm/index.html

This is the best in house unit I have seen and also is pl so it will not drift
off frequency.

Thanks, for your help.

Anyone like the Ramsey FM25 ?

is it hard to assemble. I don't solder too well.

The Veronica would be a bit pricey by the time you make it stereo.

Appreciate all the input I can get.
Thanks
John

OK. Here it is the original query and a summary of info received. I don't know if it is tacky or not but I didn't cite the people that wrote because of privacy issues. I do sincerely thank everybody that wrote.

Hello. Thanks for reading this. I have purchased an HP 8443A Tracking Generator for my 141 spectrum analyzer. It did not come with the interconnect cable, but I have managed to find all the pieces needed for constructing one. What I need know is how this cable is wired --that is, do I connect pin one to pin one, pin two to pin two, etc.? thanks again, John

First, I found that the 8553L does not have the cabling to support the 8443A tracking generator. An 8553B plug-in goes with it. I have heard nothing about the compatibility of the 8553A. Unfortunately, mine is the L version. Fortunately, the B versions are available and not terribly expensive.Win some and loose some.

It was confirmed that the connections are pin 1 to pin 1, pin 2 to pin 2, etc. Not all the pins are used.

The 8553L can be modified adding a cable from the 8552 IF section 3 MHz IF to the interconnect that is between the RF section and the IF section. A cable needs to be added to the 8553 that goes from this connection to the rf connector at the rear of the RF unit. The gentleman that told me that this mod would be hopeless without the manuals. Also, a connector plate and rf connector will need to be added to the rear of the 8553 that mates with the one inside the 141T.

Early 141T's lack the connector to the outside world required for the 8443A. I didn't get in any trouble here.

I checked with the usual vendors for a manual for the 8443A. I found only one that had it. It was way too expensive for my meager budget. If someone has one, I would love to buy it, pay for a copy or borrow it and copy it myself.

ITT Canon still manufactures the connectors with many pin variations. This info was found at their web site. I did not pursue this because I found them at Mouser.

Mouser has the connectors and pins in their catalog for RG174. I placed an order with them. The pins were in stock and the housings were back-ordered. I have not heard from them yet on the ETA of the housings.

George Kerber at glkinst@earthlink.net makes these cables.

Again, thanks all who replied.
John KC4ZXX

Hallo!

Some weeks ago I bought a Video Transmitter that can transmit the signal
from a Video-Recorder to a distant TV.
Today I opened this device and documented this with my digicam. I
uploaded the pictures to
http://www.andreas-weller.de/13cm-Video-Transmitter/
Now I have some questions:
Is it possible to expand the transmitting power of this device? What are
the 3 variable resistors used for?

Thank you!

A really simple solution would be to use a couple of 74x192 binary up/down counters. Each device takes either an up or down logic input (can be a simple push-button), and will step out a binary count. The chips can be chained to provide as many bits as required to span the frequency range you desire.

A simple example of such a circuit can be found in the old Radio-Shack "engineer's notebook".

If you are handy, you could have a breadboard design running in about 3 hours or less.

Good Luck
Bob - KA9FLX

> Is it possible to expand the transmitting power of this device?

Are you concerned about what is legal in your country?
It is possible that devices like that are already at the maximum legal
power.

If you want to increase transmitting range you could try the usual
techniques:
* Position TX and RX line of sight aimed at each other.
* Decrease or eliminate objects (walls, etc.) between TX and RX. Even if you
have to run video and audio cables over to a window, it is far less loss
than running low-power RF through walls(!)
* Investigate tapping the RF (on TX and/or RX) and sending to larger/more
efficient antenns.

> What are the 3 variable resistors used for?

I'd bet that they are NOT involved in setting RF output levels.
I wouldn't touch them without at least a schematic diagram.

The small vertical PCboard is the actual transmitter
Those tree var. resistors are part of the video modulator

increasing power is very hard to do , try to remove the RF part from the
unit build it into a connectionbox
from a real 13 cm yagi antenna and reconect it by a multiwire screened
cable
Do the same with the RF part from the reception unit

For tapping the RF from the tx and feeding it in a antenna you'l need a very
low loss coax cable , so that is not adviseble
transporting the video signal to the remote RF unit is much easier
With good 13 cm yagi antenna's over open space , even with this small power
, range cuild be 20 km and more

See if there are resistors from the emitters of the driver / output
transistors to the earth. You can try lowering their value. Do it only if
you feel lucky.. -) You can cause damage !!!
Safer bt not foolprooof: try puting a small capacitor in parallel with
them...

Be carefull and good luck..
And... let us know if it worked..

3409. FA Collins F455 FA21 Mechanical Filter with Marconi XH14 HF-SSB receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-02 19:32:28 UTC
From: Steve Lenaghan <SteveLenaghan@southwest-telephone.com>
Message-ID: <3B193F4B.BF979D40@southwest-telephone.com>
Source record: 52306

Collins F455 FA21 Mechanical Filter

Includes free Marconi XH14 Receiver !!, Filter available without radio
if requested

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1243109206

Reference for Mechanical Filter at http://www.wa3key.com/filters.html

TECHNICAL SUMMARY
Equipment Dual channel transistorized superhetrodyne receiver for single
sideband (SSB) and/or amplitude modulation (AM) operation

Type Number DOT Type No. CMC 6904 (Canadian Marconi Model No. XH14)

DOT Type approval RSS 122

Frequency Range1.6 MHz to 24 MHz

Intermediate Frequency 455 KHz

Frequency Stability
At ambient temperature of 0ï¿½ to + 50ï¿½C better than 1 ppm
At ambient temperature of -30ï¿½C to + 60ï¿½ C and +/- 10% supply voltage
better than 2 ppm

Power Requirements
Receiver circuit only 9.6VDC:150 MA
Receiver with xtal ovens: 7W average
Receiver on AC- 30VA

RF Channels 1 or 2
(2nd channel available for opposite sideband or separate frequency up to
l% from 1st channel)

Sensitivity
SSB: 0.5 uV for 12 db (S+N+D)/N
AM: 1.0 uV for 6 db (S+N+D)/N

Selectivity
SSB: 2.0 KHz at 6 db down and 6.0 Khz at 60 db down
AM: 6.0 Khz at 6 db down and 30.0 Khz at 60 db down

Spurious Response Rejection
IF (455 KHz) better than 90 db down
RF Below 10 MHz: all better than 60 db down
RF Above 10 MHz: all better than 50 db down

Radiation:
At Antenna Terminal IF: less than 1.0 uV all others less than 20 uV
To next Receiver IF: un-measurable, all others less than 1.0 uV

Speech Clarifier Range
1.6 to 4.0 MHz + 0.002%
4 to 24.0 MHz + 0.005%

Operating Temperature Range -30ï¿½C to +60 C, Warm -up period - less than 5 minutes

Type of Reception
6A3 - AM
A3H Compatible AM
A3J Suppressed carrier SSB

MeteringMeter selection of signal level or AF Line Output

AF Output 11 dbm at 5% distortion to 600 ohm balanced line
I watt at 5% distortion via loudspeaker amplifier, accessory not available

AGC Range Output varies less than 12 db for signal variations between 5 uV and I volt

AGC Response 100 milliseconds

Hum and NoiseBetter than 40 db below rated output

Long Term Stability Better than 1 ppm per month

Remote Control Provides operation of SSB/AM Mode Switch and Motordriven Speech Clarifier via the AF output line - one per receiver

Crystal Information
Beat Frequency Oscillator - 453.500 KHz
High Frequency Oscillator Crystal is selected for desired channel of operation

AM or USB
Fx = Fc - 453.5 for AM or
Fx = Fc + 453.5 for LSB

where- Fx = Xtal Frequency, Fc = Carrier Frequency

All crystals may be ordered as per CMC Drawing 188-151. Specify LSB or USB and frequency.

Voice Operated Squelch
Input sensitivity 6 db (S+N+D)/(N+D) for an input of 10 mv
Dynamic range will trigger for 7 db (S+N+D)/(N+D) worst case over a signal input range of 40 db

A coil kits is included but again first come first serve based on availability.
1.6 - 2.25 MHz, @ 2

2.25 - 3.25 MHz @ 1
3.25 - 4.6 MHz not available
6.6 - 6.4 MHz @ 3
6.4 - 9.0 MHz not available
All include Collins 455 KHz SSB mechanical filters
A manual is available for copying at cost.

All prices in US Dollars

Shipping by prepaid Canada Post minimum.
There may be brokerage charges, these are the responsibility of the buyer.

There is a $5 packing fee

AMEX and Master Card ONLY

3410. Kenwood VC-10 for a Kenwood VC-20

a corner reflector for that wavelength will be small and much easier to build
than a yagi.

3412. A simple superregenerative receiver

Hello
This is a simple superregenerative receiver. The scematic can you see on:
http://w1.409.telia.com/~u40910460/supreg.jpg
Is there anybody who can answer on 2 questions?

1.What is R6 on the schematic for? Is it only a volumecontrol or is a regenerationcontrol?
2. What components are for quenceoscillation?

Thank You

Regards
Lars

3413. Kenwood MC-60 Disassembly

Newsgroup: rec.radio.amateur.homebrew

Hello all,

Does anybody have any experience in disassembling the Kenwood MC-60 microphone? What I would like to try is to replace the stock mike element with a Heil element.

It would appear simple enough, with most similar mikes you simply unscrew the front windscreen cover to access the element. However, the windscreen on this MC-60 appears to be on really tight, and I wanted to make sure there were no hidden set screws or some other trick before I used any significant force in my attempt to unscrew it.

Thanks and 73 de W6DKN

The allowed output power in the UK is 10mW so that's probably what the tx output is, you can add a MMIC chip (4 legs) to the output to increase it to 80mW but if you've not done any microwave building/modding before you might find that difficult - the smallest of wires/legs acts like a nice inductor.

MC-50 KENWOOD - The Kenwood MC-50 is very simple to retrofit with a HEIL element. The big problem is getting it
apart. The O.E.M. manufacturer uses lots of epoxy cement on the threads, thus making it almost impossible with the bare
hands to unscrew the stainless steel 'head' or end cap. Heating that threaded area up with a hair dryer for about 60 seconds
will liquefy the epoxy and the end cap will unscrew easily. You may want to wrap a towel around it as you probabl6y will
have to use a pair of pliers to unscrew and it WILL be hot. Cut a piece of stiff foam to put back into the area where the
original cartridge was fit. Lay the HC on top and screw the end cap back in place.

3419. Problems with an interdigital filter

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-03 21:05:07 UTC
From: Peter Bolch <Peter.Bolch@t-online.de>
Message-ID: <9fe8up$9c6$04$1@news.t-online.com>
Source record: 52316

Hi

I've built an interdigital filter as described in the UTAH ATV page. Ground plane spacing of my filter is 0.35 inches, the rod diameter is 0.16 inches and the center frequency is 1.6 GHz . The side walls were made of rectangular rods, bottom and cover plate were made 0.04 inches sheet metal. All elements are brass.

As I have no suitable test equipment at the moment I did the testing with a MiniCircuits VCO and power meter. The power level of the output signal in the pass band was approx. 35 dBm below the level of the input signal and I also could not observe a clear bandpass response. What could be the reason for these effects? Wrong dimensions or relation of ground plane spacing an rod diameter? As no end plates are used with the interdigital filter described in the ARRL UHF/Microwave Experimenters Manual I left them away to ease construction. The distance from the end rod to the end of bottom/cover and sidewalls is approx.1 inch. Will this do or are end plates mandatory?

Peter

Been there - done that!

Remember 33 MHz 386s? When they were in their prime, my company produced a system using a small network of Inmos Transputers to capture radar video and do a radar to raster scan conversion to put a full colour PPI picture on a 1024 by 768 PC display. 99% of the work (interference suppression, range scaling and off-centering, radar to raster conversion) was done by 4 of the 7 Transputers in the net, each one having about the same performance as a 33 MHz 386. 4 x 33 MHz = 132 MHz, and today we are talking GHz, so guess what we do with PCs today! No flicker, variable "phosphor" persistence, screen capture, you name it - we do it.

Azimuth capture - may need customising. Incremental encoders, synchros, sin-cos pots, etc.

Trigger - not usually a problem.

Video - someone mentioned FFT, but why? PPIs are driven at baseband, but there may be a need for CFAR, swept gain, interference suppression, etc - but FFT? If you're talking MTI or Doppler, any radar with that capability has its own signal processor that does all the clever stuff anyway.

It does appear that R6, by controlling the bias on the transistor, can bring it into a region where the gain is sufficient for oscillation. Of course there is no way to tell from the values given, how much gain would be needed. No tuning component values are given.

However, L3-C4 appear to be one tuned circuit and L2-C3 (plus a couple of other parts) are another. One of these is the receiving frequency and the other, perhaps the squegging frequency.

I'm not really hot on superregenerative circuits so I'm doing some guessing here.

I currently have for sale a First Edition copy of "Radio Fundamentals" by Arthur Lemuel Albert, published in 1948 by McGraw-Hill. The 595 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Green cloth covers with gold lettering on the spine. The text covers all of the basic acoustical and electrical principles of radio. A very nice copy. Available for $9 plus $2.50 postage (book rate within the US). If interested, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

Dave

You need to see what is really going on here with a vector impedance
analyzer (S-parameter analyzer), or a spectrum analyzer with a built in tracking
generator. Your best bet is to find someone near you who works in a lab that
has this type of equipment. Even if you built the filter mechanically "perfectly", it still
needs
precision active tuning in order for it to work properly. And expect to see quite a bit of
passband loss even in a properly tuned filter of this size- the ground plane spacing does
not allow
much Qu.

3424. 38 Special IF filter help

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-04 01:35:20 UTC
From: awiecek@hotmail.com
Message-ID: <7234248e.0106031735.4489247@posting.google.com>
Source record: 52321

Hi all.. I'm in the process of building a 38 Special transceiver
from a schematic obtained at the Norcal site. I'm almost done with it, except
a few finishing touches. Radio works great except I'd like to sharpen the
response of the IF filter. The original filer utilizes only one crystal which
gives very little wrong sideband attenuation. As far as I know, there is a
provision for an expanded filter on the once available PC board. This modification
hasn't been documented on the Norcal site.
I was wondering if anyone is using such filter in their 38S and if so, would
you be able to provide me with its schematic?
My radio has been modified to operate on the 40 meter band and it uses 9.216 MHz
crystal for the IF filter.

Any help would be greatly appreciated..

Does anyone out there have a copy of the Shareware program PC Route (Printed Circuit Board/Routing program) for making Printed Circuit Boards. I had early 90's vintage version of the program (I believe it was PC Route 5.0) but through the years misplaced it. I created some PC Board with it and now need to make some modifications, but no way to edit the files. Please let me know if you have a version perhaps you can E-mail it to me as a Zip attachment.

: here.
:
: 73, Bob K6DDX
:

Like Bob, I am going to do some guessing. First, I am not completely certain
if this is a regen or superregen. I would need to see the oscillations on the
test bench. R6 is the regen control. I think L3 is acting like an RF
choke. Alternatively, it could be self-resonant and would thus could be
a Hazeltine-Fremodyne circuit. I would guess the former over the latter.
The quench frequency is probably determined by C5 and R5+R6.

Charles Kitchen is the real expert. Perhaps he will chime in.

>for these effects? Wrong dimensions or relation of ground plane spacing an
>rod diameter?

Interdigital filters can be designed to need little or no tuning. If you copied the design EXACTLY then you should see a clear bandpass response straight away.

How exact was the copy you made? The key dimensions are the *ratio* of (rod diameter)/(groundplane spacing) and the *ratios* of (rod spacings)/(groundplane spacing).

There's a program for design of interdigital filters in a BASIC software collection by myself and G4PMK, at
http://www.marsport.demon.co.uk/rf.zip

DIGIFILT.BAS is a version of the Hinshaw/Monemzadeh program published many years ago in 'Ham Radio' - same as the one referenced in the Utah ATV page - but with better I/O using MS-DOS line drawing characters. It also supports both metric and inch dimensions. This is a design program, so it will not analyse the geometry of an existing filter, but you could still use it to check whether the dimensions from the Utah program make sense.

>As no end plates are used with the interdigital filter
>described in the ARRL UHF/Microwave Experimenters Manual I left them away to
>ease construction. The distance from the end rod to the end of bottom/cover
>and sidewalls is approx.1 inch. Will this do or are end plates mandatory?

This may be part of your problem. It's not quite clear what "approx.1 inch" means. "Approx. 1 inch" would be fine - it's a standard

constructional technique to leave a large overhang at each end (say 2-3x the groundplane spacing) and not use any end walls. The overhangs acts as a waveguide beyond cutoff, and the fields at the open ends are negligible. On the other hand, "approx. 0.1 inch" would be a very small overhang, and could mean trouble due to fringing fields, or serious detuning of the end resonators if you add covers.

3430. 17mtr DSB: DSB DX!

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-04 09:48:13 UTC
From: n2cqr@clix.pt
Message-ID: <3b1b58a1.590993@news.clix.pt>
Source record: 52326

After fixing my balanced modulator problem, this week I was trying to get the audio coming out of my 17 meter DSB rig to sound, well, human. There was clearly something wrong, something very nonlinear, in the RF amp that I'd cobbled together.

Yesterday morning, as I considered my options, I remembered that the 30 meter CW QRP rig that I'd built while in the Dominican Republic had a very nice, robust broadband driver and RF amp (to MRF472s in parallel). I haven't been using the 30 meter rig very much (I really hate using the DC receiver that I built with it), so it didn't take long for me to convince myself to pull out the transmitter board and convert it into the PA for my 17 meter DSB rig.

It looked like all stages in the 30 meter rig (VXO controlled 6 watter from QRP Classics) were class A -- except, of course, the class C final. I quickly built a little diode-based circuit to lift the bases of the MRF472 to a voltage that would keep things in Class A. I disconnected the 30 meter output filter (I'll rebuild it for 17 later) and hooked the 17 meter dipole to the .1 cap that goes to the final.

The driver transistor was running a bit hot so I improvised a heat sink out of a few inches of copper tubing and some heat sink compound.

I used the microphone from an old Yaesu memorizer transceiver. I had a bit of trouble getting the mic to stay connected so I whipped out some duct tape and stuck the connector and cables right to the desk.

T-R switching is accomplished via the T-R relay that usually connects my Drake 2-B to my HT-37. So to transmit I must connect the DSB transmitter's ground lead to the Gel Cell and then put the HT-37 in transmit mode. This will all get easier, of course, when this rig is mounted in a cabinet.

This morning I had another schedule with Felipe, CU2BD to test the rig. I made the final connections with just minutes to spare. While I was waiting for Felipe to arrive on freq, I heard CT2FYI calling from Lisbon. I gave him a shout, got a good signal report (Lisbon is about 900 miles east of me!). Then Felipe came on and told me the audio sounded good. A few minutes later I worked D44BS in the Cape Verde Islands (I got a 55). Then came GB2RN on the HMS Belfast in London - he also gave me 55.

It was a lot of fun getting this thing to work. It looks like I'm getting about 2 watts PEP out. And I don't see any signs of distortion. I'm going to see who else I can work.

Next step will be to put the rig in a cabinet and build a more comfortable T-R arrangement. Then I'll be looking for suggestions on Direct Conversion RX circuits.

Thanks again to all those who've been helping out with advice and encouragement.

3432. Re: A simple superregenerative receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-04 15:57:18 UTC
From: "jack.donio" <jack.donio@home.nl>
Message-ID: <ydOS6.248594$Uo2.6041278@zwoll1.home.nl>
Source record: 52329

R 6 is the transistor bias controll , this adjust the transistor gain , so this is the regeneration control
At low level , at some point the transistor starts to oscilate and acts as a old tickler controlled receiver
at a certan point the stage starts to overoscilate , At this point , its a superregenerative receiver
at the end overoscilating is so strong that reception is zero , but at the point where superreg starts is a very sensitive receiver
for AM signals and wideband FM signals at the very beginning of the oscilation point , before superregeneration starts
strong CW and SSB cuild be received , but tuning is very tricky at this mode
IMPORTANT !! the loudspeaker must be a 150 ohm type , otherwise the BC458 will be distroyd

for 6 mtr L1 will be 1 - 2 turns L2 4 - 8 turns turns For L3 use a 10 - 22 uHy choke L4 = 100 mH or more
This receivertype is often used as a remote controll receiver in the '60
It's very sensitive for AM or pulse signals but will transmit lots of noise to nearby receivers
first 27 walky talky's used this also

Well this might not be in the mainstream of topics here but you gouys probably either know how or where to find out how to do this -

What I have is a neat old tach from an airplane. It wants a three-phase signal from a tach generator. I want to use the signal made by my sports car as an input to control a three-phase electronic generator that will run the tach.

Pointers, solutions (um, except anything using vacuum tubes), questions all welcome

From: Zack Lau <zlau@arrl.org>
Message-ID: <0MRS6.27$tK5.13336@news.ntplx.net>
Source record: 52332

I've had little difficulty building no-tune 2.3 GHz interdigital filters with a sharp knife for cutting and an accurate dial caliper for measuring. It is a bit tougher at 3.5 GHz, but I've done it.

Paul Wade described in QEX a clever technique using surplus waveguide for better accuracy of the cavity.

However, this is 80s technology. I'd imagine that products like Sonnet-Lite make it possible to design microstrip bandpass filters without spending $$$--Zack W1VT

JT, this is a good question...a neat project ...most 12 V alternators are basically 3 phase ,but the alternator usually runs at about 1.4 to one rpm ratio, forget that. I believe you can build a 3 phase pickup using a rotor with 3 magnets..drive the tach generator from one of the belts. ..output from this tach gen can be used to drive three power transistors and a transformer to give 3 phase output at about 30 vac .. simple answer is to get a regular aircraft tach gen that matches the indicator that you have...check with aircraft mechanic at local airport or get a copy of TRADE-A_PLANE publication ,they have all this stuff for sale,,planes and accessories and everything, most pilots subscribe to this ..good luck,,Harold W4PQW

I never thought about using the car alternator - with luck that just even work. The speed ratio thing might be a problem anyay - the aircraft tach generator probably wasn't 1:1 anyway.

>I believe you can build a 3 phase pickup using a rotor
>with 3 magnets..drive the tach generator from one of the belts. ..output
from
>this tach gen can be used to drive three power transistors and a
transformer to
>give 3 phase output at about 30 vac ..

After posting I thunk some more and got this far myself. The car has one of those everything on one toothed belt arrangements, so I was thinking about three bits of reflecting tape and ir pickups.

>simple answer is to get a regular
>aircraft tach gen that matches the indicator that you have...check with
>aircraft mechanic at local airport or get a copy of TRADE-A_PLANE
publication
>,they have all this stuff for sale,,planes and accessories and everything,
most
>pilots subscribe to this ..good luck,,Harold W4PQW

Plane was a Lockheed F-80 Shooting Star. Not many around these days.

Anyway, the other routes I was thinking about were:
a) get a microcontroller to take the input voltage and write software to get it to drive three function generators
b) get dc motor and drive it off the existing signal, possible with some interface/driver stuff inbetween.

This circuit has the look of something that actually works and it's always fun
and instructive to reverse engineer that type thing.

Having built regen's using 6C4's and 6AQ5's in the 50's I would say L3 is a
large inductor (millihenry-value transformer primary with terminals numbered?)
which resonates with C6 to make T1 oscillate heavily ("squegg") at an audio
rate, say ~5kHz. As Jack suggests, you want the regenerative RF oscillations
to START on the RF signal, but NOT be sustained on their own--this is the basis

of superregen receivers. For that to happen you need control over the RF negative small signal resistance looking in the collector of T1 during oscillation startup. The 5kHz oscillation provides the transitions to start up on RF noise (or real small RF signal). So I would say R6 is the super regen control which changes T1's bias--with the R6 wiper to the right, T1 is off and you get nothing out of the audio stages; with wiper to the left, T1 is active and you probably will get some squeeky sounds. In between you might get amplified noise plus detected a.m. or f.m. signals near the r.f. oscillation freq of T1 determined by the L2C3 product.

To squegg at 5kHz L3 would be .25mH.

3443. homebrew antennatuner

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-05 18:33:21 UTC
From: ON4CLN <on4cln@qsl.net>
Message-ID: <RB9T6.10968$mR5.753159@afrodite.telenet-ops.be>
Source record: 52340
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

Dear OM's and YL's

As a result of my previous posting about portable antennas, I want to *try*
to make an antennatuner myself (I'm on a tight budget).
Range: 160m to 10m, 100W max (mostly CW).

I had in mind a T-network with a coil to ground (antenna DC grounded for
static). Is this a good setup, or are there any better suggestions?
A pi-network with two coils is cheaper of course... But is this better?
And what would the values have to be?
I can twist a thick copper wire round a tube to make a coil, but how many
turns, what space between turns, and what diameter?
I have a 500pF variable air-capacitor rated +3kV I'd like to use (left-over
from previous experiment).

As a little extra, I want to incorporate my own SWR bridge / meter.
How should I do this? I was given the idea of taking a thick straight wire
(12cm or 5") between 2 PL's that will be in series with the feedline and
carry the RF, and put a wire parallel on both sides, with a resistor and a
Ge-diode to a coil-meter with a switch, the diodes being forward and
reflected power thus pointing in opposite directions.Is this a good idea, or
will this destroy the 50ohm impdedance I'd like to match to? And do I put
this right after the TRX (guess so) or after the tuner?

Once again: all input (comments, remarks, design ideas) is appreciated!

Hi dr OMs,

I just finished my packet/aprs station using a soundcard. Now i want to use my old TR2600E for this goal. However, i don't find the pin layout for the connections for the mic and spc at the top of the tr2600 anywhere. Is there anyone that can tell me where to connect TX audio and PTT ? The ground and speaker (rx output) is obvious, but i need the other two as well :)
Thanks in advance, and o yes, by the way : i found a frequency modification for the TR2600A model but i wonder if it also applies to the TR2600E model that i have here. It would be nice to be able to listen outside the 2m band, wouldn't it ?

Thanks in advance !

Hi,

6U5 valves NOS are in stock again. The label on them is 'Haltron', but
they never made valves themselves (as far as I know) so they are
obvious rebranded. They look just like an RCA 6U5.
The price is NOK 186.70 each or about US$ 20.30 I can send a picture.
E-mail me if interested

Regards,

Connectors like this have or can have 3 things. The tip is the very end
of the connector. The ring (if used) is the middle and the sleeve is
the long part. The sm is the small plug and the lg is the large one.
The sleeve is usuall the ground part of the plug.

You now need to know what goes where. Probably the speaker to the small
tip and ring.
The put the plug in and see if shorting the large sleeve to the large
ring or tip is the one that keys the rig. Then the one that is left is
the hot side of the mic.

If your car has an alternator, then you might be able to tap into it
and get an appropriate signal. They ARE 3 phase, but you didn't say
how much voltage you needed.

OTOH, this will give you the RPM of the alternator, but you could do
the math in your head, or make a new dial or perhaps recalibrate the
old one.

A T network has a high-pass response, so it's not desirable if you also
want to attenuate harmonics.
A PI network is a better choice regarding attenuation of harmonics. To
choose from them, you must take care of matching range. In this item I
am not sure which is better. I believe T has the advantage.
If you don't need to match "anything" (i don't believe T can, also),
:), just accomodate small SWR, maybe a Pi network a better choice.
Time ago I've used a PI network in my station, either as PI, L-C, or C-L
configuration (just disconnect one of the two variable caps, or at least
use one of them fully open).

It is a good one to begin with. If you need more pF, you can add fixed
caps in parallel.

You must be careful with the layout to maintain line impedance, distance
and position of parallel wires. Also it is very sensitive to frequency,
its sensitivity increase with shorter wavelenghts.
I suggest you to build a Bruene type SWR bridge, with a toroid coil.
This has also the extra advantage of work as an accurate power meter.

Just forgotten to tell you. SWR bridge goes between your TCVR and
matching network.
Right after the TCVR. You can build SWR bridge inside your matching
network, for simplicity.

TCVR >>> [SWR Bridge > PI or T network] >>> Antenna system

Good luck
Guillermo.

Hi all,

I have a R-200A power transformer
400-0-400 @ 400Ma
6.3 V @ 3.0 A
6.3 V @ 3.0 A

I would like to know If I do not use the 6.3 V Taps.
how much more current can I draw from the 400-0-400 line.
this may be for an 811A amp. I know it will run 2 tubes
but how about 3

It's poor practice to rely on a tuner for harmonic reduction. The amount of reduction you'll get will depend on the tuner settings and the antenna and rig impedances, so you'll never know if you're getting enough. If your rig is generating harmonics which you need to attenuate, it's much better practice to match the rig to 50 ohms or other known impedance, build and attach a filter that attenuates the harmonics the required amount, then match your antenna to 50 ohms. That is: Rig -> matching network if required -> filter -> tuner -> antenna. This way, the filter is always working from and to defined impedances, so the harmonic attenuation can be predicted. It's even better practice to design the rig so that no external harmonic attenuation is required. If the rig is properly designed or an outboard filter is properly used, you can design your tuner for the best efficiency and matching range without being concerned about its frequency response. Filter with filters and match with matching networks. If you try to do both at the same time you're likely to do a poor job of both.

I does work. This design was part of the Philips EE2030 electronics
experimenters kit. I build this circuit some 20 years ago and it worked

fine but it generates lots of noise interfering with reception of other radios tuned to the same station or stations close to it.

The high voltage is still rated for 400 ma. You may be able to push the ratings up slightly depending on the transformer. If the wire size on the primary is the limiting factor then you can get about another 36 watts out of the transformer. Not nearly enough to run three tubes.

Not really, it's the size of the wire AND the size of the core will
determine how much current you can pull through.

The difference, though, is not going to add the dot of an iota to the
signal received at the other end.

3461. Learning microcontrollers

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-06 17:33:08 UTC
From: w9wi@linux1.localdomain
Message-ID: <slrn9hsniu.fpe.w9wi@linux1.localdomain>
Source record: 52258

Thanks to the many folks who made suggestions on this subject a couple of weeks ago.

I ordered the Atmel prototyping kit from DigiKey along with a AT90S8515 controller. (which they put on back order until August - but they also shipped one already in the socket in the prototyping kit...) It certainly seems capable of doing what I need to do, now just to hack out the machine code to do it...

3462. SV: A simple superregenerative receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-06 17:55:58 UTC
From: Lars Brandt <lov.brandt@telia.com>
Message-ID: <O8uT6.2240$WW6.288592@newsb.telia.net>
Source record: 52259

Thanks all for the answer on my first question.
My second question was what components determine start and stop (50000khz quenchfreqency) of the superregenerative function?

And a question to Corn�. Thats correct that I have picked the scematic from a Philips experimenters kit. When I build it to for30 years ago and I didn't get it to work well because I got most sqeekie sound out of it.
I want to build it again today when I know how R6 works. I haven't the kit left today but I have a part of the instructionbook left. But I have not the partslist of the containing components. I want to know what is the value of the chokecoil (L4) in the kit? And is the value critical of the hf choke (the MW coil) after the emitter on the hf transistor?
I can't find a 150ohm loudspeaker today so I take 8 ohms instead and replace the LF stage with a LM386.

Is it correct that this curcuit can work as a clean regenerative receiver for shortwave? If you don't turn R6 to the point for superregenerative function.

Regards
Lars

Why not build an L section rather than a T. One capacitor and one
inductor
(ideally a variable inductor). A good model for this is in the 2001 ARRL
handbook.

You do not say if you have a long wire to tune or a balanced line. If a
balanced
line, try using a 1-1 balun at the input. This will be important for 160
meters
where impedances are likely to be very low. This rather than a 1-4 or
1-9 balun on
the output.

The capacitor in such a circuit should be switchable so that it is
attached on
the transmitter side of the inductor or on the output side of the coil.
You may
also wish to have a fixed capacitor, see the antenna tuner mentioned
above.

You will get some harmonic suppression from this arrangement. It is a
basic form of
high pass filter. But it will not be much.

Regards,
Ed, N5EI

3464. L.O.S.A - List of Stamp Applications [010605]

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-06 19:13:51 UTC
From: cjX@hth.com
Message-ID: <3b1cea00.63824070@news.sverige.net>
Source record: 52261
Cross-posted to: comp.robotics.misc,comp.home.automation,sci.electronics.misc,rec.radio.amateur.homebrew

Hi,

Below is the latest index of L.O.S.A and it now contains 225+
BASIC Stamp projects. You can download the complete L.O.S.A
from the following places...

WWW:

http://www.hth.com/losa/

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially Guy
Gustavson's story (see #001) about how he saved his beloved cat Kesha
gave me the inspiration to start writing L.O.S.A. I hope Kesha still
is alive and having a great life. Now 6 years later there are 225+
applications described and I hope you will enjoy reading all (or
parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa/

1.2 Why are some links dud's ?

Since people changes their e-mail and web addresses some links may be
dud's. If you previously contributed with one (or more) of the

applications please take a quick look and check your e-mail address
and/or web-links. I'm only able to keep the list updated if I'm
informed about changes, thanks in advance.

Thanks for all the reply's
Not big enough..maybe for a sweep-tube amp....but not for real transmitter
tubes
anyone play with the EL509s from Svetlana yet?
This transformer should run 2 of these.
as you all know the iron is where the cost is

This is my plan a small 40 meter tube transmitter...and a small desk top amp
that should do the trick

Dave

I am looking to get into ham what I am looking for is a schematic for a 2
meter xcever
does any one have a link for one. I am on a limited budget and could afford
to buy one but thought it would be more fun to build and this way I could
also learn more about the rig.
Thanks
Brian Hannah

3467. Re: Transformer Question

Source record: 52264

The bottom line is that 800 volts at 400 ma is going to deliver roughly
320 watts, presumably continuous duty, so it does depend on what you
plan to use it for. CW, SSB, AM, Audio???
Different tubes won't make any difference unless the efficiency of one
design is notably better than another.
-Bill

3468. FS: German 10-pin socket

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-06 21:42:18 UTC
From: arnoldg@enitel.no
Message-ID: <3b1ea481.25721539@news.enitel.no>
Source record: 52265

Hi,

I have now this weird and difficult to find socket in stock. It is
suitable for the German EL 12, EL 156, EZ 150 valves. I has 10-pins
and is made of a bakelite material. Very high quality. Brand new.
The price is NOK 107.30 /each or about $ 11.50.
I can send a picture or you can see it at my web page. It is the 10Y
socket.
E-mail me if interested

Regards,

Arnold Goksyr

> And... let us know if it worked..

Hallo!

Now I know what the 3 variable resistors are used for:
One is for the Video level. The other one is used to tune the
transmitting frequency. The last resistor alters the "channel interval"
- sorry for my bad english but I don't know the word to describe the MHz
difference between two channels :-)

I now think about building an amplifier for this module - anybody here
who knows something about MMICs? How to use them? Which gain can be
reached? Can I cascade them?

Thank you!

Andreas Weller [DM2PAW]

Brian

I'm a builder, and I really believe it is the way to get the most fun out of amateur radio, so it's a little hard for me to say this, but I don't think this is the right approach.

2 meters is a very tough place to build primarily for 2 reasons:
- construction practices are very critical
- most operation is FM which is a little more complex than, say, CW

Now, if you are in a very large city, say New York or LA, then perhaps there is enough CW activity that you could take that approach. Even sideband is not all that tough. But unless you are in a very densely populated area, non-FM QSOs on 2 meters are going to be months apart.

Not that FM is impossible to build, but when you take into account all that means, it's tough sledding.

Stability is a big issue on 2 meters, because at that frequency it's hard to come by, and in most parts of the country, the FM part of the spectrum is well occupied, so a dirty, wobbling signal won't be very well received. To get stability, you have really 2 choices; either you use crystal control and have only one frequency, or you use synthesis, which is complex and expensive.

And the cost is something of an issue as well. I know of only one decent 2MFM transceiver kit, and it costs about half again as much as full featured commercial rig. By the time you buy the synthesizer chip and a set of finals, I suspect you are already above the price of something like the Icom 2100H. By the time you bought the parts, unless you already have a really great junk box, I suspect your homebrew 2 meter radio will cost 2-3 times as much as an Icom. (I say Icom because I'm familiar with their stuff and the past couple of years they have been a slightly better buy on the low end than the other manufacturers, but Alinco, Kenwood, Yaesu, etc. aren't far off. When you get away from the cheapest 2MFM stuff, the best buy changes from day to day. And even 'best buy' is a little subjective. I'd probably rather get twice the features than save 5 or 10 bucks.)

Now you might consider 6 meters. There other modes are more popular, construction practices aren't quite so critical, and most of the cheap parts that work for HF work almost as well. You might take a peek at Jim Kortge's 6 meter homebrew rig (http://www.qsl.net/k8iqy). Trouble with 6 is that there tends not to be a lot of local activity in most places, and the band is only open sporadically, but when it is open it's a pile of fun.

Building is a bunch of fun, and it's perfectly possible to build a 2 meter radio. I just wouldn't recommend it as a first attempt, especially as your

only radio.

Oh yes, as you budget, remember whether you build or buy, you are also going to have to come up with a power supply. When you are talking about a low end 2 meter radio, an adequate commercial power supply is going to cost as much as the rig. Remember, a 10 watt FM transceiver is going to draw around 10 amps, and a 50 watt radio, around 20 (there's a lot of overhead). Here, you can save a bundle by building, or taking some alternate approach, like a car battery and a trickle charger (which has an advantage in a power outage!) This can make an HT appealing, although the low power of an HT, especially the smaller ones, and the sometimes weird antenna connections, can make the HT annoying.

I put a Heil element in my MC60 mic. Yep, it was tough to open. The head screws on but Kenwood uses some sort of hot glue to seal it tight. I got my wife's monster hair drier and heated it up for several minutes and kept twisting on it until it broke loose. Snipped the old element out and found enough foam to pack and position the Heil element just right and then soldered it in. Works great.

>[stuff deleted]

FM is virtually no more complicated than a CW transmitter. Before
the 2M FM boom of thirty or os years ago, the times you'd see FM
transmitters described in the ham magazines was because it
was a really easy way to add voice to a CW transmitter.

All you need is some element that changes capacitance with voltage,
and a very low level audio signal to modulate it.

FM receivers are sort of more complicated than a CW receiver, though
depending on the design, it may simply be different. One can pull
a narrow-band FM IF strip out of various consumer equipment, it can
be cheaper and handier than ordering the IC and filters from somewhere,
and then build the RF amplifer, mixer and oscillator to go ahead of
it. Thgat circuitry would be identical whether you are receiving FM,
CW or whatever. And years ago, plenty of hams built two-meter converters
to go ahead of their shortwave receivers, proving it can't be too
difficult.

Yes, you're just going to get a crystal controlled unit this way, but
it is a start. FOr the sake of building, it is better to build
something simple than veer towards a commercial unit because of
bells and whistles. Again, when 2M FM took off thirty or so years ago,
crystal controlled was the norm. When it got crowded enough, synthesizers
did make their entry, but initially they were external units, just like
external VFO's on the low bands. There is nothing to stop someone from
building a crystal controlled unit, and then later building a synthesizer
to go with it.

When you are building your own equipment, there are all kinds of options.
Take an IF strip out of a portable phone, and add a tuneable converter
ahead of it. Or add an intermediate converter stage, so the unit tunes
14-18MHz like in the old days, and then add a crystal controlled converter
ahead of it. Thus you get a tuneable receiver, but without the stability

problem of an oscillator running at144MHz plus or minus 10.7MHz.

In the old days, one would build transmitters that started with a six or eight Mhz crystal and multiply up. People did use VFOs at that frequency and inject it into the crystal socket. Or one could use a mixer type transmitter, with a low frequency VFO mixed with a high frequency crystal oscillator. Or nowadays, build a VCO that runs on the signal frequency, but lock it to one of those old six or eight Mhz crystals. It gives the same results as those old multiplying transmitters, but you shouldn't have to worry about filtering out the unwanted multiples of the crystal frequency. You can pull prescalers out of cable converters or even FM broadcast radios that will do the division easily.

There are all kinds of possibilities. With understanding, one can work around perceived problems.

As for critical construction practices, it's all relative. You can't be as sloppy at 2M as at 10MHz, but 144Mhz surely is less critical than at 432MHz. Plenty of people were able to build converters and transmitters for the VHF and even UHF bands in the days of tubes, when components were a lot bigger. One has to be careful, and 2M probably isn't the place to start if you haven't soldered before, but I don't think it's that big an issue. Making something small is prbably more difficult than making something that works.

Is there something inherently wrong with the Kenwood mikes that you're replacing them with Heil elements? Bill N3TVU

> Regards
> Lars
>

When I build it L3 was replaced with an air inductor I don't remember
if R3 was used. If I remember correctly L3 was 28 turns of the silver
plated 0.5mm wire wound on the ferroxcube rod with about 1mm spacing.
After finishing the coil the ferroxcube rod was removed. I suspect
Philips change L3 because the parasitic capacitance between the tightly
wound MW coil turns was to large for proper operation of the circuit.
I'm not sure what the value of L4 was but it I think it was something
like 2.5mH. In this design it's used as part of the low pass filter
(R8,C8,L4,C9) so it's not critical but it does affect the sound quality.
The quench frequency is determined by R7,C7 and R6 is used as
regeneration
control.
By removing C7 this design should work as a normal regenerative
receiver.

==========
62KOhms @25 W means a max current of approx 20 mA
If not 1 resistor ,you could go for 6 pcs 10 KOhm , 4 W or 4 pcs 15KOhm , 6
W or 3 pcs 20KOhm, 8 W + 1 pce 2KOhm , 1 W resistors in series.

Alternatively you could go for a combined parallel/series arrangement.

Look for very compact ceramic resistors on approx 25 mm (1 inch) 'stilts '
for PCB mounting .
I have quite a number for a HV supply bleeder ,15 KOhms ,5 W ,with the
resistor body measuring 25 x 10 x 10 mm (1x 3/8 x 3/8 inch)
So a bleeder for 3500 V ,16 mA would need 15 of these resistors ,dissipating
a total of 54 W ,acceptable for 15 x 5 =75 W installed , resulting in 233 V
across each resistor.

The advantage of multiple resistors is that each resistors takes only part
of the total voltage drop , hence no need for HV resistors and better heat
dissipation , yet a compact unit. And also low cost and readily available.

In the UK ,Mainline Surplus in Leicester is a good source. I bought the
above 15KOhms resistors from them for equivalent US $ 0.15 per unit.

Try this: http://www.bright.net/~kanga/kanga/kk7b.htm

By the way, though limited in frequency range, this kit has better
receiver performance and transmitter linearity than nearly all
commercial radios on this band.

And those who claim that home brew construction on the two meter band
is any more difficult than other frequencies are in very bad need of a
reality check. Are they different? Yes. Difficult? No.

Whatever you buy, I wish you good luck and have lots of fun.

Doug,

From experience I learned that planning your approach and making a flowchart
before you start writing code can save you a lot of time. Making the transision
to sequential logic is easy for some, hard for others. Your best bet is a
logical approach. (No pun intended.)

Once you get the hang of the atmel code i suspect you'll quite like it, we're using the AT90S8515 to control a very heavy (several tons) XY punch machine, due to it's mostly single cycle instruction set it can do quite a lot of work in a short space of time :) ... nice chips !

Don't forget to set the stack pointer before much else though :)

No modern commercial rig, whether or not it includes a tuner, should require additional harmonic suppression. If it does, it should be repaired or replaced. Any other rig should have a proper filter designed and installed. If ON4CLN or anyone else needs to match an antenna AND reduce harmonics, he should build a filter to reduce the harmonics, and use the tuner to do the matching.

I hate to see people limit their choices for tuners because of a problem that doesn't exist, or to try and make a tuner do a job (harmonic suppression) that it's not able to do predictably.

Hi all,
Anyone have an owners manual for a MFJ-941C versa tuner II
If you do can you zip it up and E-Mail it to me.

Thank you very much in advance.

Hi All,

What Roy says is important, but it falls short of describing what
could be confusing indications. The SWR indicator is not frequency
sensitive (except in the broad scope of HF where it does not operate
very well for VHF or LF) and as a consequence may indicate the power
in the reflected spurs!

Your tuner will only match at one of these frequencies (probably the
fundamental if you are lucky) and your meter will be left with the
same problematic indication (it is positioned before the tuner where
those spurs reside). In other words, you may have the ability to tune
a match, but your ability to observe the match indication as either a
SWR or a reflected power reduction will be negligible if spurs are
large.

Hence the issue of how high the spurs are, are what dominate this
potential problem. As most equipment already meets FCC mandates for
spurious emission, this is an unlikely occurrence. If you have
altered, broken, or old equipment (very little filtering) the problem
emerges in inverse proportion to filtering present. As Roy points
out, the problem/solution is in the rig.

Well, I havn't been in Hungary, but I'm going the Praha in about a
week. The EF 14 valves were from an old stock of valves I bought
recently - in Norway!
Hope I have luck in Praha, too.

>Different tubes won't make any difference unless the efficiency of one
>design is notably better than another.

You need to be real careful interpreting the 400 ma rating. Some transformer mfrs rate it as current drawn from the entire 800 volt winding and some rate it as DC current drawn from a 400-0-400 full wave center-tapped two-diode circuit. Quite a difference.

The limiting factor for transformer current is heat, so if the specs are not available, put a load on it for 20-30 minutes and feel the temperature. Increase the load up to the point where it's too hot to leave your hand on it. That's the max. Crude but effective for amateur purposes.

Of course there are those among us who would say crank it up till it smokes - you may join whichever group you like. :-)

A Single TV channel is 6 MHz wide.

The video carrier is offset from the bottom of the TV channel
by 1.25 MHz. Video information is transmitted in
vestigial-sideband AM.

The audio for a television receiver is always 4.5 MHz above
the video carrier frequency, for NTSC type broadcasts, and is FM.

Go to "http://www.yahoo.com" and do a search on "NTSC standard".
You will get all the infomation you can stand.

You should be able to generate a composite video signal, complete
with color burst and audio channel, with one little chip now.

Using a tuner and a filter has one nice benefit. The tuner, once
adjusted for match, will provide a 50 ohm load for the filter. This
assures optimum filter performance as both input and output circuits are
terminated in'50' ohms.

e.g. rig -> filter -> tuner -> antenna

>determine how much current you can pull through.

Nope, the core has nothing to do with the current rating. The core must have sufficient cross section that it does not saturate and that is determined by the voltage waveform (divided by the number of turns.)

The core DOES however have to have a large enough winding window to allow big enough wires to bw wrapped thru it to allow the current to flow without overheating.

The short answer is that when designing a transformer, the core is determined by the voltage and the wire gauge is determined by the current.

->The short answer is that when designing a transformer, the core is
->determined by the voltage and the wire gauge is determined by the
->current.

Ah, no sir, that doesn't happen to be true. There are two forms of loss in a transformer, both of which wind up as heat. There are core losses (eddy current losses) and wire resistance losses. In a well-designed power transfomer, both losses (as measured by heat) are approximately equal. Thus, for a given current, half the heat is generated by the wire, the other half by the core. Core certainly then is a major factor on how much current you can draw from the transformer.

>Don't forget to set the stack pointer before much else though :)

OK, what happens if I forget to set the stack pointer?
(here's where it becomes obvious how much of a novice I am at machine code!)

(I'm not directly using the stack but I do have a couple of simple
subroutines which I understand do use it to know where to return to. At
least in the simulator they do seem to be returning properly but I've not
exercised all the subs yet because of a problem in one of the branching
instructions.)

(this is a rather simple application, it's probably using less than 10% of
the capability of the device)

I ordered a 8515 at the same time as the starter kit, and was rather badly
disappointed to see they backordered it until August. Then less
disappointed when I found an 8515 in the starter kit box. And even less
disappointed when the "backordered until August" chip appeared on my
doorstep this morning... sure hope I didn't sleep through two months of
summer<grin>!

Based on your message headers, it appears that you are in the UK, so
that would be System I with FM at a 6 MHz subcarrier and the UHF
channel width of 8 MHz.

In most of Western Europe, the System B/G is used with 7 MHz channel
spacing and 8 MHz on UHF with an FM subcarrier at 5.5 MHz. The former
OIRT countries had 8 MHz channel spacing with system D/K and 6.5 MHz
FM subcarrier, although some seem to be converting to B/G.

The FM audio subcarriers are usually with 25 kHz deviation.

France is System L with 8 MHz channels and 6.5 MHz AM subcarrier and
positive video modulation :-).

I might mention that at least in North America, broadcasters generally do not transmit the sound as a subcarrier; rather, a second, pretty much separate, transmitter is used. (isn't this also the case in Europe?)

The resulting signal, on the other hand, is impossible to distinguish from the effect of using a subcarrier, and indeed when American (and presumably European?) radio amateurs transmit TV they frequently *do* use subcarriers.

PC MAX is the best for playing MP3 around the house,
its based on PC (its an addon card) so you can actually
control power and frequency with a click of a mouse.
Just need a piece of wire as an antenna...

I'm trying to move an older crystal-controlled Marine Band transceiver down to the 2m band. I just need it to transmit on 146.28, the input of our Diamond Head repeater. To xmit on 146.28, the crystal frequency should be 146.280 / 12 = 12.190 MHz. (I'm not going to attempt to re-tune the receiver stages to cover 2m; I'll use a spare scanner to receive with.)

Does anyone have a junkbox 12.190 MHz xtal they'd like to part with? I don't know any of the xtal oscillator's parameters; this is just a hit or miss project.

Thanks in advance, Jeff KH6O

>transformer.

Only half right. Core losses don't go up with current. They are only a
function of the flux excursions in the core, and this is strictly a
function of the voltage waveform.

The equal power dissipation point sounds like an economic question; I
really can't comment on that.

Source record: 52161

There are three things I'd like to try along those lines. Here goes,
in no particular order.

1) Use a PC to control the tuner. We all got one and anybody could
write a better version. Open source, of course. There are digital
I/O boards for reasonable prices.

2) The PC would also "know" what values were used in the matching
network and software could translate that into impedence seen at the
tuner output (resistance+reactance). Sort of like rolling an antenna
analyzer in at the same time.

3) Use a varactor for the variable capacitor. "Look ma, no relays."
Not the greatest idea for high power levels, just something to try.

Comments?

You need to hear the differences. Heil mics are simply the best as
they accentuate the frequencies of voice for SSB radios. If you
own an Icom, you'll also probably need a small preamp.

==========
The reponse of any mike for the range of voice freqs can be enhanced by a simple mike preamp with freq boost control.
Ref: QST -August 1989 ,pages 19-20-21 Build a Low Cost "Booster" Microphone.

The design is meant for an electret capsule ,but by deleting R1= 1000 Ohms (which provides a low DC voltage to an electret mike) a dynamic mike can be used readily.
The design involves a 2N3904 NPN transistor ,a 741 opamp and 3 presettable trimpots for audio output - low boost and high boost. A PCB Layout is included ,but the circuit can be equally well built on a piece of perf board

Making one yourself is probably cheaper than buying a Heil mike element.....and it's good fun.

> > For a screen dropping resistor.
> ==========

62KOhms @25 W means a max current of approx 20 mA
If not 1 resistor ,you could go for 6 pcs 10 KOhm , 4 W or 4 pcs 15KOhm , 6 W or 3 pcs 20KOhm, 8 W + 1 pce 2KOhm , 1 W resistors in series.

Alternatively you could go for a combined parallel/series arrangement.

Look for very compact ceramic resistors on approx 25 mm (1 inch) 'stilts ' for PCB mounting .
I have quite a number for a HV supply bleeder ,15 KOhms ,5 W ,with the resistor body measuring 25 x 10 x 10 mm (1x 3/8 x 3/8 inch)
So a bleeder for 3500 V ,16 mA would need 15 of these resistors ,dissipating
a total of 54 W ,acceptable for 15 x 5 =75 W installed , resulting in 233 V across each resistor.

The advantage of multiple resistors is that each resistors takes only part of the total voltage drop , hence no need for HV resistors and better heat dissipation , yet a compact unit. And also low cost and readily available.

In the UK ,Mainline Surplus in Leicester is a good source. I bought the above 15KOhms resistors from them for equivalent US $ 0.15 per unit.

Homebrewed GG linear amp deck consists of the tubes, coils, band switch, meters, filament xformers, variable caps. With case but no HV P.S. or blower.

Was in use for several years, then several years idle. Not set up to check it in operation at this time but it worked great before it was shut down. 1kw+ out. Tubes just checked showing no inter-electrode shorts and filaments ok.

Common GG circuit.

$175. plus packing and shipping. If interested, can e-mail photos.

Hello everybody,

I've got an OPTOELECTRONICS Handi-Counter 2300 and the need of align the PLL section in YAESU FT-480R VHF transceiver. I've got the service manual and the alignment procedure, but also a problem. Since the counter has only a low impedance imput (50 ohm) I think that direct-coupling of its input to the circuit will cause too much effect on its characteristics and will detune it. My question is, how can I measure the frequency on the test points with the counter without affecting the sensitive RF circuit?

Thanks to everybody

Unless you are coupling directly to the circuit where you are mesuring the frequency you should be ok. While this won't help you, I had a problem while trying to do the same thing to a Yaesu 757. Could not get thecounter to count as there was not enough signal. I bought a used service monitor which has a receiver rated for about 2 microvolts input to get the rig aligned.

Source record: 52170

Hi all.
I have just uploaded a small utility to automatically set any RS232 capable receiver for reception of weather satellites.

The program will also automatically record the APT audio signal from each satellite pass.

If any of you are willing to provide some feedback of what works as planned and what not, it would be of great help (and your operating system).

You will also need David Taylor's Satelite tracking program (if you haven't got it you're missing a lot) from www.satsignal.net

You need to set up an "ini" file with commands and optionally responses to your receiver. If you want, please send me this file along with your receiver make and model (and your name !!), so I can distribute it with the program.

Download the program (WX Receiver) from www.nhreas.com. Go to "Satelite" page. It's at the very top.

Thank you all in advance and I hope you like it

George Ioannu

Roberto:

I sometimes use a small coil to avoid direct coupling to a circuit.

Try making a very small coil of about 3 or 4 turns at the end of a
wire. Connect the other end of the wire to the input of your counter.
Keep the wire short, and place the coil near the test point or one of
the circuit components that are connected to the test point.

I usually don't even need to complete the circuit -- I leave the coil
just "floating" at the end of the wire. I suspect that the coupling
from the coil to the circuit is actually capacitive rather than
inductive, but it often works and gives me enough signal to count.

Hi Roberto,

Two solutions :

Depending of the RF level and the frequency, you insert a small value capacity C (1 to 10 pF for example). Yous can calculate the impedance of C by the relation z = 1/Cw where w = 2 x 3,14 x f (f in Hz). In fact you create a voltage divider got by the impedance of C and the 50 ohms input impedance of your counter. Generally the RF input of modern counters is enough sensible for getting good measurements even with a low RF level.

An other solution is to use an oscilloscope probe with a ratio of 1:10 (the internal part of the probe allows to get a high impedance). Normally the impedance input of an oscilloscope is also high (generally 1 Mohms), but you can get also good results with your counter input. Try it, it's the most simple solution !

Check for dry joint on CRT base connector and pins on HV generation
circuits. This is a common one on Tek's TAS series scopes so maybe on T912
also

Hello,

The following valves are for sale. They are unused unless otherwise specified, and mostly in original boxes. They are all in stock and can be shipped immediately to anywhere in the world.

2 pcs 3069M Large, round CRT in super heavy duty packing material each in a wooden barrel. One in

completely new, obviously never unpacked (only by me for inspection), the other one seems also to be new and unused but it has

been opened by someone. US$ 250.- each

8 pcs F16-10LD CRT by GEC (some boxes says 'Haltron' on the outside. I have not opened to verify). They

are obviously all unused. US$ 150.- each

1 pcs F16-10LD CRT as above, but made by Mullard. US$ 150.-

1 pcs F16-10LD CRT as above, but this one is used. It has a little spot on the screen. US$ 75.-

4 pcs 7BP7 CRT. The boxes says 'Haltron' I have not looked inside. Unused and unopened. US$ 100.- each

5 pcs 5FP7 CRT. The boxes says 'Haltron'. Some are opened and some are sealed. All the valves are

obviously unused US$ 75.- each

6 pcs P535/1E STC pulse modulator valve. Also coded CV 427. It is similar to 715C. All unused. US$ 50.- each

1 pcs P535/1E Same as above, but this one seems to be used. US$ 30.-

6 pcs C1148 EEV pulse modulator valve. Unused and in original boxes US$ 35.- each

12 pcs C1150/1 EEV pulse modulator valve. Unused and in original boxes US$ 38.- each

3 pcs C1166 EEV pulse modulator valve. Unused and in original boxes. US$ 40.- each

1 pcs QF 451 Ferranti. Looks like a radar TR switch and unused. US$ 20.-

1 pcs KS 9-40D Mullard klystron. Unused in sealed box US$ 20.-

4 pcs M509 EEV magnetron. Also coded CV 3982. Unused in sealed box US$ 50.- each

2 pcs M599 EEV magnetron. Unused in sealed box US$ 50.- each

1 pcs JP 9-75 Mullard magnetron. Unused in sealed box US$ 50.-

7 pcs 24B1 STC trigatron valve. Unused in original box (Strange looking valve) US$ 30.- each

11 pcs 725A Western Electric magnetron. Unused in sealed boxes. US$ 30.- each

Best regards,

Arnold Goks&#65533;yr

What sort of modulation? For an unmodulated carrier, look at some
of the surplus catalogs that carry those small TTL oscillator cans
used in computer and digital gear. I believe they do make a few
that cover the ten meter band, and the cost is minimal.

Pete

I see a new 28.322 MHz clock oscillator in my Mouser book for
$2.36. Add a simple 2N2222 or such buffer, followed by a simple
pi filter to limit harmonics will get you several mW or so without much
effort. Look to the Solid State Design book by Hayward and DeMaw
(ARRL) for some ideas on the lower power stages to follow the
oscillator--or just use the module with a simple harmonic filter
for real qrp.

Regards

Peter

Chris

Even better than the 28.322 oscillator, the Epson programmable oscillators from DigiKey let you choose the frequency. I've tried these on 15 and they work quite well. They are a little pricier than the 28.322 oscillators ($3.33 instead of $2.36) but you can pick the frequency. DigiKey is amazingly quick at shipping things, how long it takes to actually get to you depends on how much you want to pay. Here in Michigan, the lowest cost shipping generally takes 3 days from MN.

If the 28.322 is OK for you, the New Jersey QRP club has a kit, the Fireball 40, for $10 that includes the voltage regulator and parts for dividing down to get to 40 meters, along with output filtering for 40, and instructions for the other bands. You would need to come up with some T37-6 cores to make a 10 meter output filter. Having the PC card saves a certain amount of fooling around, and they even have foil for a 1 watt amp if you need a little more power. Plus, you get all the plans for the filtering which saves additional tinkering.

3538. 120/230VAC room fan running from 12VDC

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-10 16:02:58 UTC
From: Tor Tveitane <tor@bushsoft.com>
Message-ID: <9g05pg.1s0.5@bushnet.he7d26f8e.invalid>
Source record: 52185

Hi,

I am currently working in Mali, West Africa where the temperature reaches almost 50 degrees C in the hot season. To survive we need to use standard ceiling fans or oscillating room fans. However we have no grid connection here so I need to find a solution to run these fans off 12 volts solar power.

I assume that the best solution would probably be to make a hi-efficiency DC/DC converter using an off the shelf standard inductor and then chop the high voltage (170 or 322 VDC) into 50Hz variable duty cycle AC current to feed the fans. Max load would be 100 Watts.

Does anyone of know about a schematic for a suitable converter We really need the slight comfort that such fans can give us here in the bush. Please respond with any tip / URL / schematic or hint you might have.

Thanks a lot in advance for your time.

regards

Tor (TZ6TOR)

3539. Telephone Line Audio Interface

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-10 16:19:53 UTC
From: Throbber <kd6nrp@earthlink.net>
Message-ID: <J6NU6.1215$eZ6.198537@newsread2.prod.itd.earthlink.net>
Source record: 52186
Cross-posted to: alt.video.equipment.broadcast,rec.radio.amateur.homebrew,sci.electronics.design,sci.engr.television.broadcast

Hi All:

I apologize for posting this to this newsgroup, but there are probably telephone and broadcast technicians here who could help me out. Also, a ham who wants to build a phone patch interface might be interested in this.

Problem: I file radio news stories from remote locations in the western U.S. via analog voice grade lines. Sometimes my editor would like background audio (a missile countdown, jet taking off, etc.). I want to feed good quality audio directly into the phone line (I realize that an analog phone line is limited to 300-3,000 Hz bandwidth).

Here are my questions:

1. What is the impedance of an analog voice grade line?
2. How would I match the 8-Ohm impedance from my audio recorder to the telephone line?
3. The red and green wires in a telephone cord are the audio lines. Which one is signal and which one ground?
4. Could I just feed the audio directly into the line from the recorder using a capacitor to block the DC
from getting into the recorder?
5. If so, what value capacitor would I use to do this?
6. What kind of load (how many Ohms) do I have to put across an analog phone line to maintain the connection?
7. If I feed the audio into an equalizer to boost the audio below 300 Hz and 3,000 Hz before it goes into the phone line, would I increase the quality of the audio or just increase the background noise (would audio outside of the normal phone line bandwidth come across as noise)?

There is an excellent commercial product that performs this function, but it is very expensive.

Thanks,

Brian Webb, KD6NRP

The actual impedance of the phone line is several hundred ohms--
if memory serves me the typical phone is designed for around
400 ohms.

The phone line is a two-wire balanced circuit--there is NO ground
or signal. Both lines are signal.

A thousand ohms DC should sieze and hold the line. Simply use
the RadioShack telephone line transformer that they sell for a
few dollars. It is designed for 600 to 600 interfacing. Once the
transformer is across the line, it will hold and maintain your
connection, even if the phone is hung up. You don't need a cap.

You can simply drive the 600-ohm winding on the recorder side
with the 8-ohm speaker jack audio. The mismatch will not affect
quality, only the amount of maximum audio level.

An ideal equalizer would have a 600-ohm output to better match
the line transformer.

regards

Peter

Hi!

I'm refurbishing an old Henry 2k-3 amp - I have the upper deck schematic,
but no power supply schematic. I could trace it, and work on it as is - but there
are a few parts that have been *replaced* that may or may not be appropriate
in type or value.

So, anyone who can supply:

a) emailed - scanned copy
b) emailed - PDF (best!!)
c) snail mailed photocopy
or
d) URL to one on the 'net

PLEASE EMAIL TO ME!!
I may not catch your post - since the braindead admins on this system keep only
3 days maximum worth of posts up. :- (

BTW- If you happen to have any flush mount panel meters (no cut-out needed, just for the
two meter terminals) of *any value*, let me know too - the original ones are toasted here.
I'll have to work out a replacement/retrofit if I can't find any flush mount types)

Thanks,

_-_- bear WB2GCR

You can't make a silk purse from a sow's ear. (Old proverb)

1. Get your boss to buy you a laptop with a telephone modem and an audio
card with a mike input. This puts the cost where the benefit is realized.

2. Record you story as a WAV file at whatever degree of Hi Fi you wish.

3. Attach the WAV file to an e-mail and send it to your station.

4. Let the station engineer figure out how to use it. He can.

Thanks a lot, Hannu,

What about efficiency for this circuit? I hoped to have about 85% as we
don't have more energy than we need, especially in the rainy season...

As I mentioned I need to have a variable duty cycle solution, which means
that I need variable monostables at each transistor input..?

Would a DC/DC solution which convert to hi-voltage DC which are chopped up
to AC be more efficient...?

regards

The efficiency using standard mains transformers is around 80%, using
toroidal transformers around 85%. If you convert first from 12 V DC to
380V DC then chop and filter to sinusoidal 220V AC you're struggling to
get anywhere near 60% efficiency. If the fan does not need a sinusoidal
waveform in the first place the simpler and more efficient square wave
should suffice.
Why do you need a variable duty cycle solution ? Won't a standard 50Hz
drive be what the fan needs ?

3548. Sierra QRP final amp modification problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-10 19:22:34 UTC
From: lagagnon@fakesprint.ca
Message-ID: <3b23c61b.188560@news.sprint.ca>
Source record: 52194

I have just completed the final amplifier circuit modification (written up in past archives of QRP-L) to my Wilderness Sierra QRP rig. The mod involved substituting an RF choke for a 4:1 toroidal transformer, moving the 5k drive level pot from the circuit board to the back panel to make it easily adjustable, and replacing the 2N3553 final RF transistor with a 2SC1971 or equivalent.

The problem I am now having is that the final seems to go in to some oscillation(?) as I am getting weird SWR responses from a dummy load when the drive level control is set at certain levels. This is especially more evident when using the higher bands (21 MHz and up).

Any ideas out there what the problem might be would be appreciated. I am considering doing a second modification which is to change the current 2N2222A drive transistor with a 2N5109, for a better drive level to the new 2SC1971 final and wonder whther this might be the problem. However, I hesistate to make any more mods until I am sure that my problem is not something else.

Source record: 52195

Thanx for the reply . I am still a little unclear on the rules for RC in the amateur band, but you answered one of my questions. The following FCC rules are the only information I have been able find so far:

Sec. 97.215 Telecommand of model craft.

An amateur station transmitting signals to control a model craft may be operated as follows:
(a) The station identification procedure is not required for transmissions directed only to the model craft, provided that a label indicating the station call sign and the station licensee's name and address is affixed to the station transmitter.
(b) The control signals are not considered codes or ciphers intended to obscure the meaning of the communication.
(c) The transmitter power must not exceed 1 W.

Are you saying that there are RC priveleges on 6m only? Where does one find this info? I am open to the idea of making new transmitter and reciever boards, but it would sure be nice to have some schematics and timing/waveform info to start out with. Even if I make new boards I have to be able to interface to what is already there (servos, drivers, etc.). I still have many qns such as: What type of modulation does RC use? How is data sent (is it digital, PWM etc) How is data encoded and decoded?
John

I will run it a 50Hz, but most of the time I just want to run the fan at low speed. Such fans are normally delivered with rheostat-like regulators but they dissipate the unused energy as heat. As I need hi-efficiency I just wanted to shorten the AC pulses (but keep 50Hz) for running the fan at slower speeds.

Is that a bad idea...?

Thanks for these thoughts, and welcome to other hints/tips/schematics...

The Mike Sandman catalog has two different commercially made telephone line audio interfaces. One connects directly to the phone line. The other one connects to the handset cord of any telephone, and so can be used even with digital office/PBX phones and ISDN phones.

http://www.sandman.com/

While these units are NOT sold for peanuts (I think they are around $100-200, new), you might find a used on up for auction on eBay. If you were to try to build your own, the parts would probably cost about $50, but you would have to design it, test it, and put it into some kind of convenient to use carrying case.

One crucial requirement for any telephone interface is to couple the audio through a transformer, so that there aren't any ground loops. Decent audio transformers themselves are not real cheap.

If you really do want to "roll your own" check out the info on this website if you haven't already seen it:

http://www.hut.fi/Misc/Electronics/circuits/teleinterface.html

This URL is part of a much large group of EXCELLENT electronic reference pages found at:

http://www.epanorama.net/

This is not representative of real-world devices, FYI. Modern inverters
that perform a DC-DC conversion and chop to a modified-sine waveform
using power FETs can easily do better than 90% efficiency, while
powering just about any device out there.

Look around on the web -- for $100 or so you can buy a 300-400W
modified-sine inverter that'll do the job with amazingly-high
efficiency.

Why not use 12VDC fans? No inversion loss, and PWM speed control for DC is much easier, perhaps already built in.

Hi,

They may be more efficient, but they don't last very long (worn bearings and brushes). And they make a *lot* of noise.

Mains operated fans are quiet and last *almost* forever (at least compared to the DC ones). I don't know which types of 12V fans which are available where you live but in Norway (where I come from) and in Mali they have the disadvantages described above.

Thanks anyway

regards

Tor

Hi,

I originally hoped to find a schematic for a simple one of these which could
manage to convert 70-100 watts...

As I need 15-25 converters it would be cheaper to have my own PCBs custom
built and using an off-the-shelf inductor...

Traditionally done with a transformer.

> 3. The red and green wires in a telephone cord are the
> audio lines. Which one is signal and which one ground?
Both are signal. Neither is ground (at YOUR end!). Balanced line.

> 4. Could I just feed the audio directly into the line from
> the recorder using a capacitor to block the DC from
> getting into the recorder?
Not a good idea:
A) No protection for your equipment against phone line hazards (HV, etc)
B) If you block DC, you will have to have a phone off hook to "hold" the
line. This will cause unnecessary distortion.

> 5. If so, what value capacitor would I use to do this?
2-4 microfarads, nonpolar, 400V (assumes you have other circuit
requirements like HV protection and line sieze/hold covered!!!)

> 6. What kind of load (how many Ohms) do I have to
> put across an analog phone line to maintain the connection?
Enough to draw 20mA (IIRC, but you can look it up for sure!)

> 7. If I feed the audio into an equalizer to boost the

Depending on the nature of the connection, this may very well be worth the
effort to try it. However, since you get pot-luck when you dial a
connection, you may have to try several times to get a "better" connection.

> There is an excellent commercial product that
> performs this function, but it is very expensive.

There are also dirt-cheap solutions. Some are sold by Radio Shack. You could
even make your own: http://www.dplay.com/tutorial/Mac2tel.html

> line is limited to 300-3,000 Hz bandwidth).

20 years ago when I was in the studio/phone/broadcast audio biz, the standard method for improving the tinny quality of field reporters' telephone audio was a simple analogue frequency convertor at each end. A 300 Hz up-shift at the remote end and a 300 Hz down-shift at the receiving end did wonders for bass response, which is the all-important missing element (you could live with everything else). As I recall, at least one professional (reporter grade) cassette tape recorder had this built in, and there were also a few add-on boxes available.

Current technology allows you to record, digitize, compress and transmit even better quality audio, anywhere from real-time to about 1/10th real time (overnight transmission of professional quality stereo music). People doing Foley add-ons in home studios do this quite regularly with reasonably priced equipment. None of this is a do-it-yourself job, and certainly attaching anything to the phone line unless you have really decent technical knowledge is out of the question. You should be able to find something commercial for under $500, as a first guess.

Gerry

OK, this is getting a bit out of hand... ;o)

Some remarks:

1. I think harmonic surpression is ok in my portable rig (Alinco DX-70). No need for extra filtering!

2. In my "fixed" rig (TS-850SAT), I have both SWR-meter and autotuner, so the homebrew tuner should only be used out in the field "portable" ... This exludes pc-driven situations that 'll only consume power...

3. It should only do what a tuner is supposed to do: present a +/- 50ohms load to my rig's output in order not to blow the finals and to get some power out of them... Yes yes, SWR does not indicate good antennas etc etc - we know the dummy load-theory by now... But out in the field, I do not want to be bothered by all that, I just want to be able to tune the load up. I know that good designed antennas do not need tuning at all, but this means I have to take one antenna for each band or be restricted to one band. This antenna question was the topic of a previous post of mine, "portable HF antennas", but the outcome was: get a tuner - so here we are...

4. I just wanted to know if anyone had some P.R.A.C.T.I.C.A.L. hints regarding PI or T, cap or coil to ground, values etc, and would like to know to build an SWR meter / bridge myself.

I think I'll go for the "SPC Transmatch" (series-parallel capacitance), a design found in the ARRL TIS archives. Cheap and easy to build. For budgettary reasons I'll change the rotary inductor by a fixed coil with taps going to a switch.
This leaves the question of the SWR bridge / meter, any tips on that?

Thanks to all who replied so far!

One document on the topic worth to look at is
http://www.epanorama.net/circuits/teleinterface.html

> Problem: I file radio news stories from remote locations in the western U.S.
> via analog voice grade lines. Sometimes my editor would like background
> audio (a missile countdown, jet taking off, etc.). I want to feed good
> quality audio directly into the phone line (I realize that an analog phone
> line is limited to 300-3,000 Hz bandwidth).
>
> Here are my questions:
>
> 1. What is the impedance of an analog voice grade line?

The traditional impedance matching used in telephone systems
is 600 ohms matching. The telephone equipments are typically
matched to that. With modern telephone cables the real line
impedance is typically somewhat lower, but the old 600 ohm
"standard" works still satisfactorily.

> 2. How would I match the 8-Ohm impedance from my audio recorder to the
> telephone line?

Check the circuits at
http://www.epanorama.net/circuits/teleinterface.html

> 3. The red and green wires in a telephone cord are the audio lines. Which
> one is signal and which one ground?

None of those wires is "signal and ground".
Those two lines carry the signals in balanced manner.
Neither of them is connected directly to ground and neither
of them should be connected to ground by user.
Properly designed telephone interfaces which plug
to other devices use an isolation transformer
(or other electronics which does the isolation)
between the line and the audio interface. The
transformer passes audio signal, guarantees signal
balance and provides safety isolation. Usually the transformer
has lots to do with the impedance matching also.

> 4. Could I just feed the audio directly into the line from the recorder
> using a capacitor to block the DC
> from getting into the recorder?

This does not work properly. For safety, protection agains
potential audio equipment failures and best operation
use a proper isolation tranformer between your equipment
and telephone line. A 600:600 ohm telephone transformers
are suitable for this application.

> 5. If so, what value capacitor would I use to do this?

I would not recommend capacitors. So I don't give any
recommendation here.

> 6. What kind of load (how many Ohms) do I have to put across an analog phone
> line to maintain the connection?

The typical DC resistance on telephone equipments connected
to the line is 60-300 ohms. If you try to keep the 600
ohm matching a simple resistor does not do thwe job properly.
The simplest approach for interfacing is to use a "wet" type
telephone transformer which can provide he DC path
(just connect it across the line and t keeps the phone
line in off-hook condition and passes the audio signal).

> 7. If I feed the audio into an equalizer to boost the audio below 300 Hz and
> 3,000 Hz before it goes into the phone line, would I increase the quality of
> the audio or just increase the background noise (would audio outside of the
> normal phone line bandwidth come across as noise)?

I would not recommend any strong equalization. You might get somewhat
more on frequency response, but not much. And boostin too much
can lead to problems.

600 ohms is the traditional telephone world impedance to which the devices
are built to. But there are also other impedance standards, take a look at
http://www.epanorama.net/circuits/teleinterface.html#linedetails

> The phone line is a two-wire balanced circuit--there is NO ground

> connection, even if the phone is hung up. You don't need a cap.

This is a good advice. A transformer is the best solution.
When selecting the transformer for the circuit described
above the transformer needs to be such type that it can
handle the line DC current without saturation. (usually
called "wet" telephone transformers). Not all small
tranformers can fullfull this criteria.

> You can simply drive the 600-ohm winding on the recorder side
> with the 8-ohm speaker jack audio. The mismatch will not affect
> quality, only the amount of maximum audio level.

Mismatch will affect the quality. Especially on long distance
phones where bad mismatch will cause echo to line. A better
match for the same application is to put a suitable resistor
between the speaker output (very low impedance) and the
transformer. In ideal system that resistance should be
600 ohms. If you take in acount transformer losses etc.
a 470 ohm resistor would provide pretty good impedace
matching.

> An ideal equalizer would have a 600-ohm output to better match
> the line transformer.

If the equipments have 600 ohm output, then it is the best solution.
If interfacin to anything much lower impedance, a matching resitor
is a very good idea.

3570. Help for a problem concerning the TS-950SDX

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-11 13:22:23 UTC
From: Alberto di Bene <dibene@usa.net>
Message-ID: <3B24C60F.3469A87C@usa.net>
Source record: 52217

Hi all,
I swapped recently my TS-850 for a TS-950SDX.
While this latter is a very fine transceiver, on the lower band
(30kHz to 490KHz) it lacks the superb receiver sensitivity
of the TS-850, though the input front ends are quite similar.
Perusing the schematics, I saw that the TS-950 has a small
toroidal wideband transformer, L3, inserted in the signal path,
after the attenuator and just before the filters bank, while the
TS-850 doesn't.
This seems to be the only relevant difference wrt the TS-850.
I strongly suspect that this small transformer has a response that
decays considerably below about 200 kHz.

Is this old hat for anybody ? Any experience about modifying the
TS-950SDX to increase its receiving sensitivity on the lower band?
I am aware of the mod relative to the elimination of the medium wave
T-pad attenuator, but this attenuator is inserted only in the 490 - 1600
kHz band, not below.

TNX for any advice,
73 Alberto I2PHD

The thousand Ohm might work if you are near the Central Office. You
need at least 20 milliamps of current to meet standards.

>I am setting up the rig for PSK31.

Kenwood has the connector diagrams at:
ftp://216.133.235.165/Amateur/Connectors/Connectors.pdf

There's a diagram for one but not the other of the connectors (also for
the mic connector).

However, the TS-430S accessory connectors are not all that interesting
for digital modes. There is no "data input" and no constant-level
audio output. I have a TS-430S, and use the microphone and headphone jacks
(with an attenuator on the mic jack, of course) for input and output.
I listen to the audio on the computer speakers. I also wired up the
"Up" and "Down" microphone button connections to pushbuttons on my
interface box, because my radio is across the room from the computer.
I can tune the radio remotely that way.

Regards,
Dan, KB1RT

By popular demand, we decided to purchase a bulk quantity of new transmitting crystals from JAN Crystals in Florida to offer along with our *PEANUT WHISTLE TWO* 40 meter QRP CW transmitter. We've chosen the internationally recognized QRP frequency of 7.040 MHz. We are selling these crystals AT COST with the purchase of any "Peanut Whistle Two" transmitter. These are assembled transmitters and more details along with a photo can be seen at our website address below. The cost of a PW-2 with crystal is only $29.95. (Plus $6.95 shipping and handling.) Sorry - no individual crystal sales.

Sorry we don't have it up on the website yet, but we're still looking for a replacement webmaster.

Yup, that is the fuse for the low current ranges, volts, etc. There is a big Buss cartrige fuse inside the case that is only for the 20A current range. If it blows, everthing except the 20A range works. I don't know if the full 20A line current flows through this fuse or if there is some kind of shunt around it.

Some of the later 260's had a ckt breaker type of protection in place of this fuse, but mine is an older unit (like it's owner). If you pop the case on yours you will likely see this puppy.

It appears all 260s aren't created equal. My 260-6 doesn't have a 20A scale, just 10A. This scale is accessed by plugging the leads into dedicated 10A holes. Inside, there's a wire shunt between the 10A connector holes, and no fuse. The only fuse in my instrument, and on the parts list in the manual, is the 1A 3AG fuse in the battery compartment. So your "260" is obviously different than mine. Hopefully someone with a model like yours can help.

Hi Kurt
You can make a "Frozen Wave Generator" with a spark gap which will have a spectrum centered at a frequency determined by lengths of transmission lines. This can be up to 100MHz. The width of the spectrum will be determined by how many cycles you create. A relaxation oscillator at several kHz is also built into it by the discharge/charge time of the cable capacity, the HV supply impedance and voltage, and the spark gap breakdown voltage.

Hi Kurt,

Frequency range - literally DC to light (they glow). Just about
anything in between is possible.

There are a couple of approaches to frequency generation:

1) use it as a broad band noise source and filter off what you don't
want. In this form the inductance and capacitance of the holder and
electrodes determine the upper frequency limit.

2) use it in a relaxation oscillator since it will ignite and
extinguish at different voltage levels. Very useful for very low
frequencies.

3) put a lot of current through one and it behaves as a negative
resistance. If you put a tuned circuit across a negative resistance
you get an oscillator. Tune the L/C circuit and you tune oscillator's
output frequency. Commonly used on LF and HF but it works well into
the microwave region.

I'm sure there are other ways to do it, but these are the ones I have
used in the past.

Enjoy!

No expertise claimed here, but first hand experimentation many years ago confirmed that the inductance and capacitance values associated with the gap determined somewhat of a center frequency. The bandwidth was awesome, however, and some RF was being generated in the proverbial "DC to daylight" range no matter where the tuned, tank circuit resonated. As others found, tuned feeders with resonant antennas did much to enhance efficiency and in some circuits WERE, in fact, used as the tuned circuit (in determining center frequency). Using more of "no expertise claimed", here, I would imagine that the frequency limits would be set by the builders ability to construct a tuned circuit with fairly high "Q", that was also tightly coupled to both the spark gap itself and the load or antenna. (heaven forgive us here) Handfull of kHz to couple hundred mHz?

Well, I thought I had manuals for most of the older 260's on hand, but that must have been before one of the big clean-ups.
There are a large and a small fuse in some models, but I can't find a schematic of one with a 20A range, so might be talking thru my hat, here, but:

Many models have a small, one Amp fast blow fuse, and a larger, 2 amp "BBS" (whatever that means) in series. Both in series with the "Common" lead. (which is not used with the 10 Amp range).

The ten Amp range's only protection seems to be the .025 Ohm shunt across the 10 Amp leads.

Yup, thats the fuse. And I was mistaken in the amp range rating.
It is indeed 10A not 20. Now I just have to find a supplier of this
fuse that does not have $$$$ minimum order. Or maybe a 1/4" bolt might
do the trick........ :-0

Thanks to all for the responses.

Thread:

On the subject of cascading a harmonic supression filter with an antenna tuner.

The watchword is... "One can never have too many poles!" Heh, heh.

All is not as rosy as Roy indicates.

Most ham radio "tuners" are basically single frequency devices. They are simply not broadband devices.

Lossless filter networks suitable for harmonic supression are usually designed to work into a broadband fixed resistive load, say 50 Ohms over their whole frequency range.

This frequency range includes not only their passband but also their stopbands.

If the terminating impedance in the stopbands is not the specified resistance, say 50 Ohms, then their stopband attenuation response will not be as theoretically predicted.

And so...

Just because you adjust an ASTU "tuner" connected at the output of a harmonic supression filter for a VSWR 1:1 indication on a 50 Ohm VSWR indication device does not mean that the filter sees 50 Ohms looking into the tuner towards the antenna at all frequencies.

Most ham radio "tuner" settings for VSWR 1:1 result in a 50 Ohm match at only one frequency.

The impedance looking upwards towards the antenna through the tuner at all other frequencies, especially in other frequency bands, for that 1:1 setting will be all over the map!

Hence the harmonic supression from the harmonic supression filter will not be as good as theoretically predicted simply because the filter does not "see" the 50 Ohm termination in its' stopbands that it was designed for.

In practice, this makes accurate harmonic supression problematic at best.

Most modern transmitter designs overcome this by using harmonic supression filters that far exceed the actual harmonic supression requirements in their stopbands, in the "hope" that if they do not see their design termination impedance in their stopbands they may still effect enough harmonic supression to do the job. But this cannot be predicted since the narrow

band antenna tuner can only effect a 50 Ohm impedance at one frequency.

A situation of "overdesign the harmonic supression filter and hope".

Caveat emptor.

This is one of those "it all depends" things.
With my voice characteristics it would be a waste of money. The stock mikes
work just fine for me.

The only way to tell is to try them side by side and see what kind of
difference you get, if any.

Um, a shunt is not a fuse. It's a calibrated piece of wire across which
a voltage is measured which is proportional to the current through the
wire. Give it the wrong resistance, get incorrect readings on the 10A
scale.

Yup, and the shunt doesn't seem to be any protection at all. In fact if it
were to fail open, the meter and it's protection diodes would likely be
toast quite soon. Sorry 'bout that!

> 600 Ohms is common for interoffice trunks. 900 Ohms is common for
> subscriber lines

The actual subscriber line impedance specified in different countries
have varied somewhat. The other impednace references might have
been more wirely used eariler, but in Europe 600 ohms is now a
norm used for general telephone equipments and modems
(NET4 specifications). The equipments connected to public telephone
network in Finland and many other European countries
must meet NET4 (ETS 300 001) technical specs. All
power specs and return loss measurements are taken so
that the reference impedance is 600 ohm resistive.

Here is some more technical information on this topic at
http://www.epanorama.net/circuits/teleinterface.html#linedetails

Telephone line details in different countries

Normal telephone line is theoretically designed to be 600 ohm
resistive impedance. This 600 ohm is kept as international reference
for designing telephone line equipment
(typically the signal powers are measured to 600 ohm load). In
practice the telephone line does lot look like pure 600 ohm
resistance. The cable and equipments used by the
telephone companies have effect what the real impedance is.

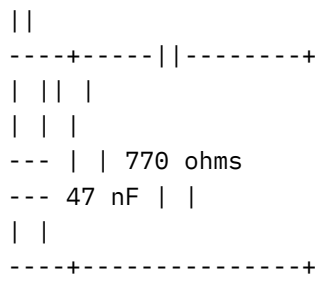
Telephone equipment which is designed to operate with 600 ohm loads will operate with those real-life lines, but it's performance is worse than in ideal situation. Typically the modems are designed for 600 ohm reference impedance because they can handle the sidetone, but for best performance the telephones are designed to the exact line impedance.

When best performance is needed the circuit should be exactly matched to the impedance of the real telephone lines. Matching the hybrid circuit to the real line impedance (instead of 600 ohm) will improve the feedback typically by 3-6dB. 20dB sidetone is easy to achieve, but 30dB is also not too difficult provided you can measure the line impedance and take steps to build a correct balancing network.

Different countries have different characteristics on the telephone line parameters. Here are some impedance models for typical lines in different countries:

USA

Normal telephone subscriber lines in USA (0.4-0,6mm subscriber PE insulated vaseline filled cable) are 770 ohm resistor (with 2uf series capacitor) and 47nF parallel capacity.

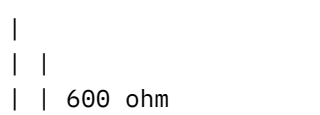


This diagram is referred to 800Hz, but impedance is rather complex, and varies from high value at low frequency and drops to ca. 150 ohm on 10kHz and 120-125 ohm above 100kHz.

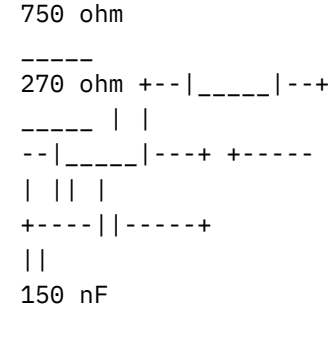
Some telephone lines can have higher impedance (typically 1100 ohms in lines with loading coils or telephone air cables).

Finland

The equipments connected to public telephone network in Finland must meet NET4 (ETS 300 001) technical specs. All power specs and return loss measurements are taken so that the reference impedance is 600 ohm resistive.

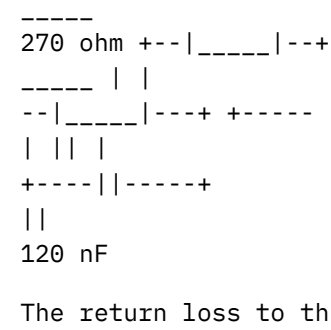


The return loss of the terminal equipment must be greater than 10 dB when compared to 600 ohm reference. This measurement applies to telephones, modems and other terminal
equipments. NET4 technical specs are European specs and they are used in many European countries (NET4 is actually a collection of different specs in use in different
countries). Telecommunications Administration Centre in Finland also mentions in it's regulation THK 20 I/1997 M that the telephone line equipment can be measured against
the 600 ohm resistance mentioned in NET4 or complex impedance of Z = 270 + (750 //150 nF). Here is a picture of that complex reference impedance:



Typical cable used in for subscriber lines has following characteristics: 0.5 mm diameter wire, loop resistance 182 ohm/km and pair capacitance 39 nf/km.

Because the telephones designed to meet the needed characteristics measured against 600 ohm reference impedance does not always work satisfactory when connected to
telephone switches. A better results can be obtained if the phone meets all other NET4 regulations, except the return loss is matched to TPL06 regulations. The reference model
used in TLP06 for telephone line:



The return loss to this reference model must be greater than 15 dB.

>me, but ....

Depends on what frequency the radar was using. I don't know what the
dimensions for that particular can was, but I guess that with typical
coffee can sizes, the resonance would be somewhere in the 1 .. 3 GHz
area and as far as I know, the speed traps use much higher
frequencies, so I doubt about that story. Although, using a smaller
can might work.

Spark gaps have been used to generate microwaves for more than a
century, since Lodge and Bose and some others experimented with
oscillators, waveguides, horn antennas and cavity resonators at the
end of the 19th century. In Wireless World (September 1979) there was
an article "Victorian microwaves" about these experiments.

3600. FS: Old Radio Books

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-12 18:17:50 UTC
From: oldbooks78@aol.com
Message-ID: <20010612141750.11902.00004080@ng-fc1.aol.com>
Source record: 52246

I currently have for sale the following old radio related books. Postage is for book rate within the US, at cost elsewhere. The books are:

Orr, William I. "Radio Handbook, 17th Edition" published by Editors and Engineers, Ltd. in 1967. Cloth. No Jacket. The 847 page hardbound book is in very good condition, clean with no page tears or pen marks other than a previous owners name stamp inside the front cover. Strong binding, nicely illustrated. Available for $8 plus $3 postage.

U.S. Naval Training Schools "Basic Radio Notes & Communication Circuits" published in Chicago: Original Wraps. No Jacket. The 147 page softbound book is in good+ condition, clean with no page tears or pen marks other than a previous owners name inside the front cover, and again on the page ends. The covers are a little chipped along the spine, but everything holding together nicely. Not dated, but looks to be c1950. Available for $8 plus $2 postage.

Hornung, J.L. "Radio Operating Questions and Answers, 10th Edition" published by McGraw-Hill, 1950. No Jacket. The 588 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Blue cloth covers show quite a bit of wear, but the cloth is not torn, and everything is tight and secure. Available for $6 plus $2.50 postage.

Siegel, Hy "All About CB Two-Way Radio" published by Radio Shack, 1976. Soft Cover. The 112 page softbound book is in very good condition, clean with no page tears or pen marks. Nicely illustrated. Available for $4 plus $2 postage.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

Dave

If it's anything like my 95 neon, you remove the housing around the front, remove the radio with two or three screws holding it to the dash in front and pull. You'll find two cables an antenna cable and possibly a ground. The power/speaker cables are available at Radio Shack (tm) or at least they were a couple years ago. I'm working on an in-dash radio for the Neon that will receive amateur bands.

AFAIK the lowest police radar frequency range is X band around 10.525 GHz.

But the RF modualtors used on most video gear do actually use a
subscarrier,
usually a free-running 4.5 Mhz L/C oscillator.

Source record: 52052

I work at a place where we deal with everything from 20 ma 24 volt current loops to 460 3 phase at a couple of hundred amps. Saw a demo video from the Fluke meter company. They use a special fuse in their meters. It is rated at a low current but it will break several thousand amps of current. The demo was you have your meter set for a ohm or current range instead of a voltage and get it across the 460 volt line. The common fuse can blow but create an arc just as an arc welder. The circuit is not broken. The leads melt under the tremendous current and if you are holding one in each hand as many do then you soon fry. The special fuses are built to interrupt the very high currents and not create the arc.

Thanks to thieves and vandals it's not usually obvious
how to get them out. This is by design.

On many cars you must use special tools to release hidden
latches, and then the radio slides out. That was the
case on my car's original radio (1986 VW Jetta with the
OEM VW/Heidelberg radio), and on the CD player I recently
installed in its place.

You might want to sneak a peek at the service manual
before you break things.

You know.. its one thing to spam a group when you are constantly updating a page with new content and you actually have something on there new and interesting to look at but your page hasn't changed. Its still the same..

I know what you'll say.. go read the FAQ... blah blah blah

Why would I want to goto your page, just to give you another hit, just to read you FAQ?? Who cares...even though you only SPAM the group about your page once a week, its still bugs and annoys people cause there isn't anything new and it gets old after a while! REALLY OLD!

>Ya, but... I'm *sure* the spark xmitter is *rich* in harmonics!

At 108 km/h (30 m/s) the doppler in X-band is 1 kHz, thus, the
receiver bandwidth is only a few kHz, so any discrete harmonics from a
jamming transmitter would have to hit that passband.

When you put the spark gap in some form of cavity, it will have a
resonance at the fundamental and other resonance modes (not necessary
an integer multiple of the fundamental in an irregular shaped
resonator), so in order to generate a strong signal in, say, X-band
with a coffee can, some of these higher resonances would have to fall
into this band.

Even with a broadband white noise source covering, say, 1.. 25 GHz a
quite large total power is required, in order to get sufficient power
into the 10 kHz receiver bandwidth.

While the received power in a radar is inversely proportional of the
forth power of distance and the power from a jamming transmitter is
proportional to the inverse square of the distance, so jamming a
simple radar at large distances is quite easy.

However, speed traps are usually operated well below the maximum
distance in order to be able to identify individual vehicles, so there
is not much you can gain from a long distance jamming device.

Paul

As Bob mentioned, sparks have some interesting characteristics, but to a first approximation, they are simply a switch which can be used to shock-excite a tuned circuit. Charge up a cap, and suddenly connect (through the spark) an inductor across the cap. You get E^2*C/2 energy per spark. The higher the Q of the tuned circuit, the narrower the bandwidth of the resulting oscillation, but it will always be a damped oscillation (unless you use the negative resistance feature of an arc: you might do a search for info on "Poulsen arc"). A spark forms rather quickly: the rate of change of current is quite high. So it can shock excite resonances up to rather high frequencies, as another thread has pointed out, though from what I know of sparks, I'd expect it would become rather inefficient up in the GHz range. In the tens of kHz range, where spark transmitters were used commercially for some time, transmitters with net efficiencies around 50%, up in the 100's of kW range, were built. There have been some nice historical articles in Electronics World+Wireless World magazine in the past ten or fifteen years about this subject.

Cheers,
Tom

Richard,

Most of the small straight through units sold for CB in the metal box with
SO-239 connectors on each end work just fine at 6 meters. I see them
sold under a zillion different names like Vanco and such.

The basic unit I'm talking about is the rectangle unit with a simple
meter, fwd/rev slide switch and a sensitivity knob. The same unit also
worked as a field strength meter by screwing in a small whip antenna into
the jack at one end above the chassis connector.

Approx size was about 3" by 3" by 7" long ... all the controls and meter
on the top. Hard to beat the preformance of this well designed unit.

cheers
skipp

This 1kHz (doppler shift) is the frequency difference between the radar xmit and
rcv frequency. The predetection bw could be much wider; probably on the order
of a few GHz unless they put in a BPF. A spark gap pulsing at 1kHz could
produce a signal that the PLL in the radar would lock up to and think that this
1kHz was the doppler frequency. In that case you'd be better off pulsing at
500Hz or whatever corresponds to the speed limit. In any case this is all
hypothetical and I don't think they have email in jail!
I think the first radar speed traps were at 2.4GHz before there were microwave
ovens.

Resistive return-loss bridges work well for stuff like this.

A design I've used is in the VHF/UHF DX Book, edited by
G3SEK (a fab book: buy it!). I made a complete unit with
a Mini-Circuits VCO, with outputs for a frequency counter
and a volt meter. With leaded resistors that I graded to
1% with a DMM it worked fine beyond 2 meters. With SMD
resistors it would be good to microwave frequencies.

You know....its one thing to piss and moan about something that you have
no control over like the weather but to constantly piss and moan about
something YOU DON'T HAVE TO READ is pathetic.

Send me mail Matt if you can't figure out how to use Outlook Express.

Even YOU Matt can put Charles Johnston into your filter and ignore him.
Why you haven't yet is a mystery.

You and your CJ whiner crew spend more time pissing and moaning over
Johnson and waste more bandwidth complaining than Johnson ever used. Why
is that when one entry into your filter would resolve the issue?

Tell one thing Matt. Do you really read EVER post in EVER newsgroup you
subscribe to? Must take a lot of your time to read EVERY POST?

Also I have noticed real spam in the last few days on the NG but not once
do I see Matt complaining about these? If you read every message and are
so dead set on stopping spam why are you silent until Johnson posts?

Again, if Outlook Express is really kicking your butt as it seems, drop
me a line and I'll be more than happy to help you learn how to properly
use your newsreader.

Glenn

3625. Tayloe Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-14 01:02:54 UTC
From: W3JDR <j.r@usa.com>

Dan Tayloe's (N7VE) commutating quadrature mixer has been issued US Patent #6,230,000 (http://www.uspto.gov). This is an intriguing & simple circuit that offers direct-to-audio conversion, very high dynamic range, inherent high Q bandpass response, and quadriphase audio outputs...all with only a few parts! The circuit is just crying out for someone to build it up, evaluate it, and report on the results. Has anyone taken a look at this yet and tried it out? If so, I'd like to hear about your experience.

Anyone making, selling, or using a patented item is infringing. I see that the patent has been assigned to Motorola, Inc. Has Motorola given permission for anyone to make and use the circuit? If so, where has this permission been published?

Amateurs have been experimenting with the Tayloe mixer for well over a
year now (for example, there have been many reports in 'Technical
Topics', RadCom).

It gives very good results in a direct-conversion SSB receiver with a
polyphase analog phase-shift network, and I'm sure some people are
already using it with DSP.

Seems like that particular genie is already well out of the bottle...

I could be accused of blowing my own trumpet on this one (the link below
;-), but here goes:

Have a look at http://ironbark.bendigo.latrobe.edu.au/~rice/ssb/ssb.html

It makes nice SSB at frequencies up to about 5MHz using cheap LS and CMOS parts.

This was originally published in February 1998 in "Amateur Radio", the
Journal of the Wireless Institute of Australia, the worlds oldest amateur
radio organisation (founded about 1910). (So if anyone tries to take me to
court for patent infringment, I can claim "prior art" ;-)

I am amazed that the US patent office would patent this. As far as I know,
commutating mixers were well known in Australia prior to 1979. I first saw
them described in course notes from the Footscray Institute of Technology
in 1979.

A serious literature search in a real library, not the web, will turn up
dozens of reputable papers on commutating mixers/modulators. I did this
years ago, thinking I had discovered something new & wonderful and was
going to collect many academic "brownie points"[1]. It turns out that I
hadn't & I didn't, but then I really enjoyed developing my own SSB exciter.

[1] Brownies - a youth organisation common in England, Australia and New
Zealand. If you have never heard of 'em, then the joke is lost on you. It's
no fun if you have to ask.

Now, I think I will get a US patent on the resistive voltage divider.
Should be easy.

73 & have fun.

I do not know what the exact patent rules are in the US, but in other
parts of the world you can build one for evaluating purposes, but not
sell it. For this reason, patents are often written in a way that it
is hard to duplicate, but the patent should still be able to limit
the use of derived ideas as widely as possible.

I have to once again state clearly that I'm not a patent attorney. But I'm certain that in the U.S., there is no protection until a patent has issued. That is, anyone has been free to publish or experiment with the circuit (unless it qualifies as a trade secret, which seems unlikely given the publicity it's apparently gotten) up until the time it's patented. But then it's no longer o.k. to make, use, or sell it in the U.S. without the patent holder's permission. The fact that people published, built, or even sold an item before a patent issues doesn't, as far as I know, cause any dilution of the patent holder's rights. A patent itself lets an invention "out of the bottle", since it's public and is required to provide detailed information about the patented item. Once a patent issues, anyone with the required skill has enough information to build it. But they're not allowed to. That's essentially the exchange between the government and the patent holder -- the patent holder has to provide complete and public information about the device in exchange for the excluse rights to it for a limited period.

Of course, a U.S. patent has no force that I know of in the U.K., and in any case I know patent laws are quite different in other parts of the world.

What are you using the spectrum analyzer to measure? They are not necessarily the best instrument to use to measure frequency. They are designed to show relative strength of signals within a frequency spectrum. If you are using it to check the level of the spurs and harmonics, it shouldn't matter if the oscillator frequency is pulled off slightly. If you are trying to measure frequency, use a freq. counter and make a probe out of coax by stripping off about 3-6 inches of braid at one end, leaving just the center conductor and its insulation exposed and put an appropriate connector on the other end to hook up to the freq. counter. Hold the exposed center conductor just near enough to the oscillator to get a reliable reading.

The problem:

I need a probe that I can attach to a spectrum analyzer that won't load down the circuit (operating at 130 Mhz) under test and can be built for less than $20.

I have a 100 Mhz probe for my scope, which has a 1M input. It loads the circuit down and changes the oscillating frequency substantially.

With active probes costing over $2k.. What do ya do if you need to look at a circuit under test with a 50 ohm spectrum analyzer?

Patents are protected from the date of APPLICATION, not from the date of PUBLICATION. "Patent Pending" is not put on millions of items every year for nothing!

OTOH, copyright material is covered from the date of PUBLICATION.

> That is, anyone has been free to publish or experiment
> with the circuit

You can experiment all you want, but I wouldn't publish such material without advice of a real IP lawyer.

> ... up until the time it's patented. But then it's no longer o.k.
> to make, use, or sell it in the U.S. without the patent holder's
> permission.

The prohibition is on SELLING (or actually "exploiting") the IP. The law says nothing about hobbyists building things for themselves. Why do you think they are published for everyone to read?

If you look up any pattent (including mine) you will see that dozens to hundreds of subsequent patents refer to it. Do you think those subsequent patent holders didn't experiment with concepts in other patents?

> Of course, a U.S. patent has no force that I know
> of in the U.K.

Most IP of any value, particularly if owned by or assigned to multi-national corporations has protection in place (or pending) in most countries. And copyrighted IP is covered in most of the world by the Berne Convention.

If the "you can't even build it" rule actually applies to me building one (assuming I can come up with a working device from the material in the patent), and then using it (for no financial gain), then it is essentially an unenforceable and absurd law in any case.

Roy, I respect your technical expertise and I really appreciate your willingness to share it with us on a regular basis. However, it is my own personal opinion that nobody in a "homebrew" newsgroup would give a hairy rat's hiney for your legal opinions on homebrewing.

Now, as the original poster asked...has anybody played with this thing (especially at VHF and above) and gotten decent results?

Yes, and you also have about 3 to 5 pf of input capacitance that is driving your oscillator nutzy. You say you want "high" input impedance. If it is purely resistive, how "high" does it have to be? Don't say you want a megohm, because that just isn't going to be possible. Can you stand 1K of loading? 500 ohms? What is your bottom limit and we can go from there?

Your scope probe probably has a 1M resistor in it alright, with a capacitor shunting it to trim the square wave response. So it's 1M at DC and something else at 130 MHz.
>
>With active probes costing over $2k.. What do ya do if you need to

This depends on what you are trying to accomplish. If you are looking for relative amplitudes at various parts of the circuit, then you do need direct coupling and you might need an active probe. Since absolute power measurement isn't (shouldn't be) what you're after, a simple FET follower would probably do the trick.

If, on the other hand, you are simply wanting to see the harmonic level or noise performance, you might just use a non-contact probe, i.e. a piece of wire to pick up the radiated signal.

The bottom line is that we need more insight into what you are trying to measure.

I don't think anybody reading this newsgroup has such little intellectual
curiosity that
a patent disclosure would stop him/her from experimenting. If anything, patents

inspire experimentation. But thet assignee of the patent does have the
right to stop you from building the circuit if he invokes it.

I looked at the patent and noticed 2 things,

1. You still need the 90 degree phase shift at i.f. (audio) which is
always a major pain;
2. The 4 paths of the SP4T switch have to be matched in amplitude
and phase to obtain good carrier and undesired sideband rejection.
To achieve 40dB would require phase accuracy of +/-0.5deg. and
amplitude matching of +/-.08dB, a little tricky in a lot of ham shacks.

The convention these days is to digitize the input by sampling
at 4x the the carrier with a single a/d, do the polarity reversals
and decimate by 2 digitally into 2 paths which are then baseband I and Q.
These I and Q streams represent cosine and sine multiplied versions
of the signal you downconverted.

see http://www.graychip.com for some help if interested.

It would be a good idea to build the circuit but not sell it.

Wow, I got a lot more interest generated here than I thought..

The problem: I'm building a AM airband receiver circuit. I have
access to a 1.5 GHz spectrum analyzer. I have access to a 100 Mhz
Scope and regular passive probes. I don't really care about absolute
voltages, I just need to know what frequencies and relative strength
I'm dealing with and not load down my circuit.. Adding 5-10pF of
capacitance to a 100+ Mhz circuit makes a big difference.. No
frequency counter.. The 100 Mhz scope lists frequency and the
spectrum analyzer marker will ID frequencues, but I have no dedicated
frequency counter.

Now, I wish I had access to an active probe.. As I recall, the Agilent one was $2000+.. Not an option -- amazingly the place doesn't have one. The spectrum analyzer is used mostly to look at CATV systems. I'm thinking about building a FET to a CC.. The FET for the high input impedance and the CC as a buffer between the FET output and the 50 ohm input.. Any thoughts?

Additionally, the room the equipment is in is electrically noisy.. I tried putting a clip lead with BNC near the part of interest (non-contact) and I picked up a lot of unwanted signals/noise.

I am looking to observe the frequency response of the unfiltered input of a FET (attached to some wire as an antenna.), then observe the output of the FET, then a filter stage before entering the mixer. After the mixer stage, I'm at 455 kHz and things get a lot simpler.

The spectrum analyzer is 50 ohms, the FET is 10M... So if I attach the spectrum analyzer directly coupled to the FET or even a 2k output stage, it's going to see tiny amounts of signal.

How much loading can I tolerate? In the oscillator stage, not much as it will lower the Q and possibly prevent oscillation from occurring.. Other parts of the circuit will take tolerate more but it will change the frequency response some.. If I can load the circuit as little as possible, it's all around better..

I appreciate y'all giving it some thought...

My postings had nothing to do with my opinions on homebrewing, or for that matter my opinions on whether patent laws are reasonable. They consisted only of statements of what the law is, in the apparently mistaken assumption that someone would be interested.

I see that you're not interested in knowing what the law says, and you're probably right in your implication that nobody else on this newsgroup particularly cares either -- especially if it might inconvenience them in doing what they want to do.

So have fun, folks. Ignorance is bliss. I won't bother you further with the petty details.

Source record: 52093

The simplest solution is to connect a resistor to the center conductor of a piece of small coax and run the coax to the spectrum analyzer. Use a 1/4 watt or smaller resistor. Make the connection from the resistor to the coax as short as possible and use the other resistor lead for the probe tip. The hard part will be to make a good short connection from the coax shield to ground near the point being probed. A 5.1k resistor will give you about a 100:1 voltage attenuation (40 dB). This won't be very rugged, but it's cheap and you'll get good results.

Your scope probe has a capacitance of around 10 - 13 pF. (If it's a Tektronix probe it'll give the value right on the probe or compensation box.) at 130 MHz, 13 pF represents an impedance of less than 100 ohms. This is what's loading down your oscillator.

Hi, Dub-ya,

Any time you are working with high frequency oscillator stages, you're going to have the problem of loading by a scope probe or by the input of a 50 ohm instrument.

If your passive probe is loading down the circuit, even in 10x mode, and you can't get access to an active probe, you will have to measure your oscillator's frequency at the output of a buffer amplifier in your device under test, if there is one.

If there isn't, you'll have to measure the osc freq indirectly, by injecting a signal of a known frequency, then probing the 455 kHz IF with that scope probe and doing the math (The sum of RF + IF = LO). Be sure to use the marker count feature of the spectrum analyzer when you measure the frequency because depending on your needs the marker may not be accurate enough in normal mode.

Good luck.

R,

Al W6LX

Source record: 52095

As usual, I find Roy's comments informative and useful. Roy documented a good source for his opinion. This most certainly is a homebrew relevant topic. Contrary to the view expressed by another poster, I do care.

However, on this subject, I believe that Roy's interpretation is too severe.

From the reference Roy mentioned --
"The right conferred by the patent grant is, in the language of the statute and of the grant itself, ï¿½the right to exclude others from making, using, offering for sale, or sellingï¿½ the invention in the United States or ï¿½importingï¿½ the invention into the United States. What is granted is not the right to make, use, offer for sale, sell or import, but the right to exclude others from making, using, offering for sale, selling or importing the invention."

My personal interpretation of this is that the patent holder has the right to exclude me from making, using or selling his patented item. But I also believe that you or I are not scoff laws in building or experimenting with one. If he advises me that he does not want me to use the item in my experiments, then I should stop.

Aloha,
John KH7T

If all you want are frequencies and relative amplitudes,
why not just attach an antenna to the spectrum analyzer
and place it in the vicinity of the circuit?

I'm not. The US patent office, as best as anyone can tell, is manned by a gang of howling idiots. If there's a limit to what they will accept as a valid patent claim, nobody I know has been able to find it yet.

Remember, these are the rocket scientists who brought us the Amazon 1-click patent. :(Not to mention the gem at http://www.delphion.com/details?pn=US05443036__.

It's rapidly becoming impossible to do any software development work in the US without running afoul of one or more bogus patents that would never have been granted by an examiner with two brain cells to rub together. Let's just say that the days when Einstein walked the hallowed halls of the USPTO are clearly over.

I agree with Jim, I really respect your opinion on all things radio but I just got off the phone with my brother who is a corporate lawyer. Although not a patent lawyer he has worked with companies on patent issues and according to him the part in the patent law that reads "make or use" only applies if you have commercial "intent". However the law is fairly (read, how a lawyer or judge wants to interpret it) clear on "experimental" use. As long as my intent is for experimental purposes I can build it and use it. It's kind of like having and using a satellite descrambler. I can use one as long as it is for experimental use only. There is a kind of fuzzy area here though. If my experimental unit has a commercially available equivalent then I am required to buy the commercial version. But in this case where the unit in question is a circuit that is part of larger whole how do you determine the commercial equivalent? The answer is. . . . . you can't without a lot of lawyers and courts. So unless the company that has the patent is Disney and as long as your intent is experimental the question of weather or not the law is being broken is going to remain in that fuzzy area.

As I said my bother is not a patent lawyer and may not have the right angle on this so I would like to hear from someone, maybe even the US patent office about this.

Too much stray electrical noise in the room.

I'm thinking that I may just need to design in some buffer amps.
Designing in 6 cheap transistors and coupling that to the spectrum
analyzer is starting to sound a lot more viable.

place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society

Where is all this noise in the room coming from?
You can usually ignore that sort of crap on the analyser screen, and
concentrate on the wanted signal.

No, not at all.

In the U.S. only the inventor can apply for a patent. But he has to apply no later than a year after the first public disclosure (e.g., publication). If a patent application isn't filed within that year, then no one can patent the item. But a patent typically takes several years to be awarded after the application is filed. It was during the period between the first public disclosure and the time the patent issues that I was talking about.

In the U.S., patent applications aren't public. So no one except the applicant even knows the details of what has been applied for, and there's no protection until the patent actually issues. (And what actually gets patented is often not very similar to what's in the original application.) When the patent does issue, the fact that people discussed or built it during the time it was pending doesn't dilute the rights of the person to whom it's assigned.

Evidence that the patented item (that is, the thing described in the patent's claims) was publicly described more than a year before the patent application was made can be used to have a patent declared invalid.

This process and these rules are very different in many, maybe even most, other countries. I believe that in some countries, a patent can be obtained by the first person to apply, whether or not he's the inventor. But not in the U.S.

Roy Lewallen, W7EL

DISCLAIMER: I'm not an attorney, and this isn't legal advice. If you need legal advice regarding patents, see a patent attorney. I'd appreciate corrections from a knowledgeable person if anything I posted above isn't correct.

Yes you usually can, and in most of the cases when I use a spectrum analyzer I'm looking at a CATV system, it doesn't matter what crap is out there because the cable signal is quite strong as compared to any noise courtesy of the sheilding provided by the cable.. And the amount of stuff that gets in is so small that I can easily write it off.

In the "lab room" where I'm working on this circuit.. Noise comes from a variety of sources, nearby building motors, other electrical equipment, computers, and if I could couple directly to the circuit, I could probably wipe most of it out.. Unfortunately, I can't easily couple to the circuit without loading the circuit down and supply the SA with a 50 ohm or so input it will like.. Which is where I'm interested in solutions. I've gotten some interesting ideas from the group and look forward to experiementing with them.

Dear Roy,thanks for the info. The American system sounds quite fair. I understood that Phil Rice, VK3BHR, had something to do with the Tayloe Mixer. I built his "Fourth Method SSB Exciter" in 1998 after his article in 'Amateur Radio' of Feb. 1998, and it works fine, exactly as he described it. The VFO must be four times the transmitting frequency, and I use a DDS 0-60 MHz with a 100 Hz step, which is 25 Hz in the transmitter. In his article Phil describes how to use the mixer also for an RX, but I have not tried it, yet. Instead, there was an article with the same mixer in the Hungarian ham magazine 'Radiotechnika' 1998/5, which I tried to make, but was not satisfied because here in Europe we have very strong broadcasting stations (Free Europe etc.) which penetrate through simple receivers, so we have a background concert when listening to the amateur bands. Superheterodynes are still a must here.

Someone told me that electrical diagrams cannot be patented, only their concrete realization, a product, but I am not sure. Best wishes,
Bozidar, 9A2HL

Speaking of publishing, I noticed the schematic diagram for the tayloe mixer and a nice technical discussion about how it works in QEX Mar/Apr 2001 edition Page 61.

This letter did not mention any patent, or any suggestion to not use the information for non-commercial use. Considering that it was written by Dan Tayloe, N7VE, I took it to indicate that using it for personal experimentation by amateurs was allowed.

There is a probe that works nicely for most of my measurements. It is a 450 ohm resistor built into a 'scope probe' body so that is has less than 1 pF of parasitic capacitance.

The probe forms a voltage divider with the 50 ohm analyzer input which works out to 20 dB attenuation. That allows reasonably accurate power measurements while not disturbing the frequency resonance of the circuit. True, it is loading the circuit by 500 ohms, but for anything other than an oscillator tank it isn't too drastic.

This is a low enough impedance that it doesn't pick up much radiated signals from interfering sources.

The nice part is this probe works, more or less, up to microwaves. I have used it up to 1.9 GHz and it gives useful information even at those frequencies.

This probe is available from DigiKey and probably a lot of other places I would imagine.

Try a fet or dual gate fet amp, easy to build, and certainly repeatable success. A 3sk88 works well with 10nf in and out coupling. 100k g1 to gnd. About 3volts or so on g2 Use a pot if you wish, but also have 1-10nF to ground from g2, and an rfc in the drain. Also a 220 ohm in the source in parallel with a 1 nf. This is from memory, but worked well, had gain and a flat response. At least the loading with this will be constant, and you can reduce the input coupling with a small cap as ther is about 20 dB gain from memory.
I have the exact cct somewhere....?

Let me help clear some of this discussion up with som direct knowledge. I have been in communication with Dan Tayloe, N7VE, since November of 2000. I have been developing a Software Defined Radio using Visual Basic and the PC sound card. I first ran across Dan's design through a Google search. I dropped him an email and he has been as helpful and open as anyone can be. He even sent me the schematic last year and I sent him several articles from QEX that were relevant to commutating mixers and commutating digial filters but none were identical to his design. An article in QEX even went into great detail about why 6 dB is the minimum noise figure for mixers that physics predicts. He subsequently sent a letter to the editor relating to some of those articles and published his schematic. This you will find on page 61 of the Mar/April 2001 issue of QEX.

With regard to patent issues, Dan has given me permission to use his design and to describe his circuit when I present my SDR design paper at the Central States VHF Conference on June 30. After I recently learned of his patent I dropped him an email to ask what his intentions were. He said that there is no problem with experimental use but he said and I quote, "Just don't try to make a few million dollars off of it. :)" I am sure that if any of you are serious about experimenting, Dan will be happy to communicate with you. Some of my friends are interested in using if for weak signal work so we will be looking at VHF and above. I will drop Dan an email and tell him to start reading this thread.

I built the circuit earlier this year first on a breadboard and then in protoboard form. It really does work well. I do not have the test equipment to verify the noise figure but for 1V in I get roughly 1V out of the detector. I can also put 4V in without distortion when I use a 5V part. I plan to layout a PCB soon so that I can get reliable performance. I expect to be able to go to 30 MHz on receive with 74AC series parts in the clock circuit. ECL should allow higher frequencies.

Let me clear up another misconception, this is NOT a mixer although it has some of the characteristics. It is really a quadrature commutating digital filter. Therefore it does not generate the sum frequency that a mixer does. This is why it does not have the high loss/noise figure (6 dB+) that a mixer does. I have done a lot of reasearch and I have not found anything exactly like it. It is NOT a commutating mixer. Those have been around forever and they generate both sum and difference frequencies. This is a very high Q quadrature bandpass filter operating at the carrier frequency, which is in DSP terms equal to Fs/4 (sampling rate divided by 4). In DSP when you do downconversion at Fs/4 you do not have any loss in the mixer either because you simply change the sign every other sample like this 0,1,0,-1,0,1...

In the real design implementation there are NO resistors (ignoring the 2.5 ohms of the paralleled multiplexor switches) until you get past the first ultra low noise op amp. That means you have no resistor induced noise before the gain stage. This is an improvement over what you see in the patent.

Phil Rice, VK3BHR, refers to a design of his in an earlier post. He states on his web page at:
http://ironbark.bendigo.latrobe.edu.au/~rice/ssb/ssb.html...

"This switching modulator should be capable of acting as a demodulator. This would require reversing of the direction of signal flow through the circuit. The problems expected in doing this are firstly that attenuation through the sequence network would prevent the reception of microvolt signals. Secondly, to obtain 40 dB of opposite sideband suppression, the signal level through the analogue switch would have to be held below 0.05 volt peak to peak. This would result in a poor dynamic range."

The problems Phil mentions are not an issue in Dan's invention. Also with DSP you can easily correct for phase and amplitude imbalance in software.

If you are interested in experimenting with the Tayloe Detector (NOT mixer) I will be happy to put you in touch with Dan and to share my expriences with you. I would also love to communicate with anyone interested in PC based Software Defined Radios.

I hope that this helps to clear the air on some of the questions in this thread. If you have questions please feel free to email me at gyoungblood@seedstage.com. I don't normally read news groups but a fellow ham referred me to this discussion because of the Tayloe discussion.

Happy experimenting and 73,
Gerald Youngblood

Ok. I have now read all the threads. Quite colorful. :^)

Good defense in this note, Gerald! I don't think enough people understand the detector well enough to understand why it is not an ordinary commutating mixer, and how it is different from all the other commutating mixers that have ever been done.
It sounds a lot like a regular mixer. I simply gave up debating the point with one fellow who just didn't get it (and likewise thought **I** just didn't get it).

I saw Phil Rice's article for the first time about a year ago. It is not the same, but it is similar. However, as you have pointed out, his circuit was not useful for either weak signal nor high dynamic range receiver work, where as mine has been optimized for both.

Now on the subject of permission:

I do not own this patent. I surrendered my rights to Motorola, and I am not empowered to speak for the company. As such what I say carries no more weight than what Roy says.

However, I will offer my humble opinion. It seems like it all comes down to "What is in it for me?". Motorola is in the business to make money. Motorola will lose no money by anyone experimenting with this detector.

On the contrary, if experimenters use this circuit, find it useful, and publish positive results, that will greatly increase the probability that some commercial interest will want to use this detector in a high volume consumer application. Such an application could in turn generate Motorola royalty revenues, thereby profiting Motorola.

People experiment, Motorola wins.

I therefore see no business reason why Motorola would discourage the experimentation and promotion of this detector, since it seems to be in the company's best interest, and there is no profit to be gained from discouraging such experimentation.

I have no idea what Motorola's interest threshold is here, but selling a few hobby kits is likely way below that threshold. However, if serious commercial revenues were to be made on the application of this invention, it would eventually get their attention.

Try MicroMart for small ones.

3675. Tube receiver book

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-16 17:51:51 UTC
From: Rick Haub <rhaub@midwestmicro-tek.com>
Message-ID: <3B2B9CB7.B92EF22C@midwestmicro-tek.com>
Source record: 52123

I got my novice about two years ago and the first thing I did was to build a McCoy designed transmitter. Next I built an HB receiver. The receiver worked ok but I decided after viewing a number of designs and reading a lot in the 1967 R. A. Handbook that I could design and build my own tube based super regenerative receiver using only parts from my junk box (even though I only got my ticket 2 years ago, I have 25 years worth of collected tubes, transformers, caps, resisters, switches, etc). Well after a lot of trial and error and building some test gear I managed to pick up some signal on the 40 meter band. I am presently designing in mods for BC, 160, 80, 20, and 10 meters. I learned a *lot* by doing this on my own.

Now my question, even though I learned a lot I know there is a lot more to learn. . . . So, is there a good, definitive, step by step book on how to build, test and trouble shoot tube based receivers?

The question I've most wanted to ask you since I first saw this nifty
circuit: what got you started in this direction? What were you looking
for or experimenting with that eventually led you to do this design?

> for or experimenting with that eventually led you to do this design?

Actually what got me started in this direction was the availability of the TI 74CBT3253 high speed analog mux and a 3000 mile (Phoenix to New York) cross country drive. I had lots of time to do nothing but think and ponder. The 74CBT3253 is a zero delay analog mux (as opposed to a high delay digital gate) used to connect microprocessor address and data lines to different banks of memory. It was never intended for analog use, but it works quite well for that task.

I knew about audio switched capacitor filters using an input resistor and four capacitors which were switched at a 4x rate. The input side to the mux ends up exhibiting sharp bandpass behavior, based upon the R/C time constant of the single R and multiple Cs used.

The idea of an active RF bandpass filter on a receiver front end is what got me started. Since we now had a *really* fast dual 4:1 mux part, perhaps I could do some active RF bandpass filtering using the switched capacitor filter in front of a receiver mixer rather than a simple fixed tune bandpass L/C.

The really neat thing about this is that if I combined the VFO and IF BFO signals together at a 4x rate, this narrow active RF bandpass filter would track the receiver tuning. This should enhance receiver performance on congested bands such as 20m (contests) or on 40m with big adjacent SWBC signals.

I pondered this and the fact that if I was using a really narrow rf active filter, the signal I really wanted was at an offset of 600 to 800 Hz, and if I tried to do 4x at that offset frequency, I would likely be injecting a really strong signal on top of what I wanted to listen to. I pondered this aspect quite a bit.

In order to produce the necessary 4x clocking for the rf switched capacitor filter, it would be necessary to combine the BFO and VFO together and then produce a composite 4x signal (maybe using a PLL or a

bunch of exactly synchronized DDSs... a bit complex but manageable) to drive the filter.

In order to simply test the idea, I decided upon a scheme to use a direct conversion receiver as the test bed. Then it would be simple since the 4x signal used for the RF switched capacitor filter could be divided by four and used for the direct conversion mixer VFO.

Much simpler! A direct conversion receiver would not be optimum, but it would allow me to test the idea before trying the more complex 4x clocking trick on a superhet receiver.

It was then that I started thinking (I was still driving) about what the signals looked like on the switched capacitor filter at zero beat to an incoming RF signal, which would be four equidistant points on a sinewave, stationary. Then I thought about what they looked like when not exactly on frequency: each of the four outputs would drift slowly tracing a sinewave at the difference frequency, each formed of RF samples taken 1/4 cycle apart, each output then being 90 degrees apart from each other.

I suddenly realized that the switched capacitor topology could be used as a detector (no separate direct conversion mixer required), that it naturally produced all four phases of output, had bandpass characteristics, and that the input RF signal was being "integrated" on to each of the four capacitors through the input filter R, so that only difference frequency appeared and not the sum. Lastly, I realized that the new detector seemed to capture the peak RF voltage, and thus have a low detection loss (under 0.9 db conversion loss).

Since I have read about the R2 phasing receiver, I began to work on receiver designs based upon that approach (two branch I and Q audio combined using 90 degree phasing shifting to given single sided reception). I have been working on incrementally making improvements to the basic design for several years now. I am on my 4th generation design, and there are still ideas to try out and improvements to made. I am trying out new modifications this weekend.

I never returned to pursue the RF active front end receiver filtering aspect. There is only so much time in the world to experiment! It might not work the first time, but problems are simply engineering opportunities.

I doubt you'llfind a small inexpensive one that will handle the .100
stuff.
That needs a larger radius bend. Probably a different sort of machine.
If it is important that it handle the thicker metal you might want to
make sure what you find will do it.

A good way to learn to program microcontrollers is to start with PC assembly language. X86 assemblers are to be found on the net and there are good books such as "Peter Norton's Assembly Language Book for the IBM PC". What you learn about PC assembly language and BIOS/DOS programming is not wasted. Microprocessors are mostly variations on the same theme. Any old PC will do to learn on (including XT, which is what I learned on), so cost is insignificant. At any rate, if you're reading this then you more than likely have a PC. Still, an old boat anchor PC is a good for the purpose because there is some risk of corrupting disk drives when you start playing with the BIOS in assembly language.

I'm not sure I'd go along with that.

Especially if you learn real-mode assembly on an old XT, a great deal of the time spent in learning x86 assembly language will actually be spent learning about platform-specific weirdnesses like MASM/TASM/GAS syntax, segment:offset addressing, and register quirks (which registers can be used as addresses, which registers are used as implicit input/output values for various instructions, etc.) Absolutely none of this knowledge will transfer to any other processor besides the x86 family, and even then, the rules change drastically when you compare 16-bit real mode, 16-bit protected mode, and 32-bit flat model coding.

Yes, you'll nail down the concepts just fine this way, but I'd suggest learning x86 assembly only if you really have nothing better to do with a large chunk of your life. At this late juncture, it would be best to avoid learning/using assembly at all. It's not a very scalable skill.

Boy, I'm with you John.

Not only does the Intel X86 have a lot of "weirdness", but it's quite a complex instruction set machine. Not only does this make it hard (relatively) to learn, but all of the microcontrollers are RISC machines. The exact antithesis of the X86.

On top of that, the X86 (and all PCs) are von Neumann machines. Most of the microcontrollers are Harvard Architecture machines. Again, quite a different animal.

Now there is no doubt, that the discipline in learning and using assembler on an X86 can be transported to microcontrollers, and SOME of the algorithms you use can also be transported (but surprisingly few). But it's a bit like learning rocket science to understand how to use a garden hose. Why take the hard path?

The PIC series of microcontrollers, probably the most popular for amateur use, have only 35 instructions. Compare learning that to the 400+ instructions for an X86 machine!

You can get the chips cheap, you can generally download very competent development environments for free, you can build a programmer for next to nothing, and there are hundreds of examples on the net to learn from. The hard part is making the decision to dive in!

There's a bunch of useful links at

Gerald, I for one, and perhaps others, would be interested in the circuit details of your improvements to the Tayloe mixer. The more I read about this mixer, the I am convinced that it is the way to go for future receivers.

3697. 17mtr DSB - schematics and pictures

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-18 09:56:27 UTC
From: n2cqr@clix.pt
Message-ID: <3b2dcfa8.4900573@news.clix.pt>
Source record: 52144

I put the schematics and some pictures of my 17 meter DSB rig on my
Web Site: They're not pretty, but I hope they are legible.

I'd appreciate it if you guys could look at this rig and let me know
if you see anything that I could do to improve performance. Not that
I'm unhappy -- I have VKs calling ME. But if you can see anything that
might improve things, let me know.

The final and the driver get a bit hot after a long transmission.
They were designed for CW operation, and are now obviously dealing
with an entirely different duty cycle. I've bolstered the heat sinks,
but wonder if there is anything else I could do.

Feedback is appreciated:

Just click on the 17 meter DSB link at:

Hi, Brad,
I think the LT2001 was TRW's version of RCA's overlay process 2N5109.
A pair can be used in a doubling oscillator to generate up to 100mW at 2.5GHz.
The specs should be similar to the 2N5109, i.e., high Ft over a wide range of
Ic.
The die is bonded to the steel header of the can so you can heat sink it better
but this is also the collector.

I seem to remember the LT series devices originally being made by a small
company that TRW probably bought out.

3699. impedance of a coil

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-18 16:00:13 UTC
From: ram <rmilne@aa.mbn.or.jp>
Message-ID: <9gl83ditg1@news.mbn.or.jp>
Source record: 52146

I am trying to make the Clive Smith (G4FZH) RF modulated noise bridge as described on page 71 of "Test Equipment For The Radio Amateur" published by the RSBG in the UK.

White noise from a zener diode (which can be optionally modulated by a TLC555) is amplified through an AC-coupled 3-stage common emitter chain and the output is passed to a homebrew coil. The input side of the coil has 2 connections and the output coil is center-tapped and forms the basis of the noise bridge. (The antenna with a shunt capacitor is balanced against a variable capacitor/variable resistance and noise minimized by a receiver connected across the bridge).

The advice for making the homebrew toroid transformer is to use:

A. FT50-6 dust iron core, 4 windings, each 14t, or alternatively....
B. 596100001 ferrite core, 4 windings, 6t each

Within the text it says "use 4 lengths of 26swg enamelled copper wire about 120mm long, twist them together and then thread them through the toroid to give five or six turns evenly spaced to cover the circumference. Divide the turns into two pairs, each pair consisting of two windings connected in series, the end of one winding connecting to the start of the other."

I have 3 questions.

1. From the above description, I get the image of the input coil (which is not center-tapped) now going around the toroid circumference 2 times (the 2 wires were twisted together and wound around once - then the end of one wire was connected to the beginning of the other in "series" so electrically the input coil now goes around the toroid twice). Is this image right?

2. Why are we twisting the wires together? Wouldn't it make more sense to space them evenly side-by-side as you wind them?

3. I'm not sure whether I can get hold of the toroids suggested. If I have to cobble something together with another toroid, is there any way that I can measure my creation to make sure it has the right performance characteristics for the job. (This is the first time I've made an RF noise bridge.) Does this coil need resistance/impedance within a certain range? Do I have to worry about flux saturation like a power transformer? If I can learn how to measure this correctly then I am quite prepared to keep experimenting with homebrew coils until I hit on something usable.

Thanks in advance for your advice.

Best rgds, ram

3700. FS: medium-voltage power xfmrs.

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-18 16:57:29 UTC
From: Brad Thompson <brad.thompson@valley.net>
Message-ID: <3B2E32F9.475F92F5@valley.net>
Source record: 51997

FS (several pieces available): MV power transformers.

These well-built transformers feature dual isolated primaries for 110/220V, 50 to 400 Hz operation and three isolated secondaries.

Why a 50 to 400 Hz frequency rating? I'm guessing that these transformers were intended for a test instrument, but these transformers run fine at 60 Hz.

An electrostatic shield (grounded via a white lead) isolates the primaries and secondaries.

Secondary 1 is NOT center-tapped and presents a resistance of 197 ohms, an open-circuit voltage of 160VAC, and 148 VAC into a 2.7K resistive load (approx. 54 mA). The color-coded leads are red and red/white and measure approximately six inches, as do the transformer's other leads.

Secondary 2 IS center-tapped and presents a resistance of 0.7 ohms center-tapped, an open-circuit voltage of 18VAC, and 16.4 VAC into a 9-ohm resistive load (approx. 1.8A). The color-coded leads are yellow (2) and yellow/red for the center-tap.

Secondary 3 IS center-tapped and presents a resistance of 11 ohms center-tapped, an open-circuit voltage of 39VAC, and 34VAC into a 91-ohm resistive load (approx. 0.37A). The color-coded leads are green (2) and green/yellow for the center-tap.

The core measures 1 by 3 by 2.5 inches and is comparable with a rating of approximately 80VA. Using the 10-percent secondary-drop currents, I arrived at a conservative 50VA guesstimate power rating.

Overall dimensions are 3 inches high by 3 inches deep by 2.5 inches wide. Mounting centers are 2 inches by 1.75 inches. The leads exit halfway up the transformer's end bells, making this tranny ideal for breadboard or above-the-chassis mounting. Thus, there's no need to chew a large hole through that steel chassis you've been saving for years-- and dreading the prospect of mutilating via hand drill, file and elbow grease.

Further cosmetics: the transformers are finished in glossy black paint, with the winding diagram neatly (and incorrectly) stenciled on one end bell. Whoever designed the stencil got the secondary color codes slightly wrong, so please print a copy of this e-mail for reference. There's no vendor name-- only a cryptic "MD-3555-C" part number emblazoned below the wiring diagram.

Okay... now for suggested applications: use the 160V secondary to drive a full-wave bridge rectifier (I'll include four 1N4007 1KV 1A silicon diodes gratis with your order) to produce approximately 180VDC at 45 mA DC. If you don't already have one, get a copy of DuncanAmps' PSU Designer freeware to design this-- and other-- power supplies.

Energize one or two 35L6-GT heaters (35V at 150mA) with winding 3 and feed the plate(s) from the DC supply. Use one 35L6 as a crystal oscillator or VFO and the second 35L6 as a PA. No 35L6s in your junk box? Try 35B5s, 35C5s, 35A5s, 35GL6s, etc.

In receiver apps, you can use one 35L6 as an audio amplifier heated by winding 1, and use winding 2 to light off four series-connected 5U8s to do receiver-related things, or try 17EW8s, 17X10s, or 18FW6s. Use your imagination-- and some of those oddball heater-voltage TV tubes you bought for a song at the last hamfest!

Other possibilities include powering a gas-panel display, a batch of analog op amps, and a clutch of logic for a frequency display.

I'm asking $7.00 each plus postage for three pounds per transformer to your QTH. Need more info or a postage quote? Don't hesitate to drop me an e-mail.

73--

3701. cheap waterproof emergency transmitters?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-18 21:52:49 UTC
From: Ian Upright <ian-news@upright.net>
Message-ID: <62usit89b1op542pd6k5le0cpunsl9m226@4ax.com>
Source record: 51998
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.homebrew

Hi, we have several hundred people who sail and windsurf in the bay of Vancouver, and a number of small sailing clubs, and a small rescue team. What we are thinking about is getting some small, waterproof, inexpensive radio transmitters, or to build our own transmitters, and using some directional technology to locate the distress. The transmitters would have to be waterproof, so I guess we would have to make some sort of waterproof container to hold them in.

First of all, do any such inexpensive radio transmitters exist? (I was hoping in the US $20-30 dollar or less range) Possible? The transmitter would probably just send out some kind of pulsed tone or beacon, we wouldn't need voice transmission or reception. Maybe one type of transmission for non-critical emergency and a different mode for very serious time-critical emergency. The transmitter should probably work when the rubber ducky is right at sea level, and have about a 3 to 5 km range, line of sight. What kind of wattage would be required to do this? Use 9v batteries perhaps?

We would probably monitor our own frequencies (not sure what kind of frequencies we would be using), but in our case, they would be mostly used in potentially life & death situations so if it was an issue of legally using the frequencies we probably wouldn't care. :) The frequency probably doesn't need to be monitored by the costguard & such but it might be a possibility to use frequencies that they may monitor -- although we may not want to bother them with less serious emergencies such as a boat that is simply overturned and needs assistance in getting upright.

If anyone has ideas about:

1) sources of already existing inexpensive radio transmitters that would fill our needs
2) schematic/designs for inexpensive & small radio transmitters with some type of beacon transmission
3) ideas of what frequencies we should be using for this
4) where to get, or ideas on how to make cheap small waterproof cases

That would be helpful!

Ian

3702. Re: Tayloe Mixer

Ralph,
I agree with you that this is the way to vastly improve the performance of receivers of the future. The improvements over the patent are really Dan's. The main thing that is different from the patent is that no resistors are required on the op amp inputs and the op amps are used in true differential mode. The RC integration is provided by the 50 ohms of the antenna and the sampling capacitor which is selected for the bandwidth of the filter (usually .33 to .47 uF). Since the R is duty cycled at 25% the impedance seen by the input of the op amp is actually 200 ohms. So the first stage audio gain is Rf/200. The bandpass filter bandwidth is BW=1/Pi*200*C. I am using a Linear Technology LT1115 Ultra Low Noise Op Amp in my circuit that at 200 ohms input yields only a couple of dB noise factor.

You should feel free to contact Dan directly. I am sure he will be glad to tell you more about the design.

3703. FS: microwave PC board laminate

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-19 00:44:57 UTC
From: Brad Thompson <brad.thompson@valley.net>
Message-ID: <3B2EA089.FD7047E9@valley.net>
Source record: 52001

Hello--

I'm offering a batch of microwave-grade printed-circuit
board laminate. Previous batches have sold quickly, so
e-mail me to reseve your choices to avoid disappointment.

73,
Brad AA1IP

****

Taconic Plastics, Ltd. p/n TLE-95-0100-C1/C1

PTFE/glass dielectric of 0.01 inches thickness and dielectric
constant of 2.95 nominal. Laminated with 1-ounce copper on both sides.

Supplied in 9-3/8 by 18-inch panels separated by sheets of anticorrosion

paper (some edge discoloration is present). Note that this thin and
flexible laminate will require extra care in processing.

Price: $10.00 per piece; or $20.00 for three pieces, plus $4.80 for
insured priority-mail shipment (U.S. only). Please add $2.00 postage
for each increment of three additional pieces (e.g., postage for six
is $6.80; nine is $8.80, etc.). Canadian purchasers, please inquire for
postage.

Also available in boxes of 50 sheets-- please inquire for price and
postage.

****
I accept payment via personal or cashier's check or money order drawn
in U.S. dollars and made payable to "Brad Thompson", or via certain
credit cards.

Warranty policy:

If you purchase these boards and find them unsatisfactory upon your
visual
inspection, notify me within seven days and return in as-received
condition
for a full refund of your original purchase price (you pay return
postage).

This material is subject to prior sale and is supplied as-is, as
new-old-stock
(NOS) merchandise, with all responsibility for safe and successful
application

residing solely with the purchaser.

**********Available from:**********

3704. Re: impedance of a coil

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-19 01:08:29 UTC
From: Bob Camp <bob@cq.nu>
Message-ID: <hCxX6.84434$tR.8888893@news02.optonline.net>
Source record: 52002

Hi Ram,

I don't have a copy of the article you refer to, but the gizmo you are working with sounds like a balun. Based on that here are some answers:

> 1. From the above description, I get the image of the input coil (which is
> not center-tapped) now going around the toroid circumference 2 times (the 2
> wires were twisted together and wound around once - then the end of one wire
> was connected to the beginning of the other in "series" so electrically the
> input coil now goes around the toroid twice). Is this image right?

Yes, you have either 28 turns or 12 turns on this winding.

> 2. Why are we twisting the wires together? Wouldn't it make more sense to
> space them evenly side-by-side as you wind them?

The idea is to improve the coupling between the windings. More or less you are trying to turn them into a transmision line.

>
> 3. I'm not sure whether I can get hold of the toroids suggested.

This presents a problem. I would suggest trying the normal parts sources and see if they will sell you a couple of cores. Over here we have several outfits that will sell you a small kit of cores or a few cores at a time. I would try very hard to get the cores that they used in the article. The two cores you mentioned are pretty common. I would be surprised if you could find anything else that would work any more easily.

Assuming you can't do that here's what you do - you need a core that is good in terms of loss for the frequency range you will be working over. Core saturation and that sort of thing should not be a major problem unless there's a lot of DC running through one of the windings. The core has to be big enough to put enough wire on to give you a single layer inductor with the same inductance as the original design. Going to a bit smaller wire may help if you have a core that's *almost* big enough but don't go to far. Very small wire (number 40 or so) will probably mess up the frequency response. I have used video display rfi choke cores for this kind of thing in the past, but you may need some test gear to tell if you have it right.

The simple thing to do would be to put as many windings on what ever you have as you can and then try it out. If it's ok at the low frequency end but falls off at the high end pull off some turns. If it runs out of steam at the low end then you probably need a larger core.

Hope this helps.

Ian,

I realize this isn't something you want to hear, but it does need to be said. Radio transmitters are licensed /approved items. Even for the best of purposes they are government regulated and the red tape involved in making them is pretty major. You may want to get in touch with FCC or DOT (depending on the end of the bay) and see what they have to say. I agree that a life is a pretty important thing, but you could have everything confiscated before it ever got to that point. After you finished paying off all the fines it could cost a whole lot more than $20 a radio.

The following is ON THE GROUND and ready for pickup in Western NY. (west of Rochester)

The tower is used but in very good shape. It has been down and stacked for about a year.

A few sections that were "on the ground" do have discoloration and SLIGHT rust, nothing serious.

You could put this tower up tomorrow and enjoy many years of great service.

Current price on the following is approx $10K.

SALE PRICE $2600.00

Qty Description P/N

1 Base Plate BPC55G
1 Top Plate APL55G
18 Rohn 10' Sections 55G
14 Torque bars TB55
15 GB55
13 KC192
29 Turnbuckles
2 Guy Plates
2 Torque Arm Stabilizer Assembly TA55
1 Set of Anti-Climbing sheets 455ACL-3
3 5' Pipe (2") mounts w K156 brackets DM55G2
and mounts at each end.

1 5' Side mount consisting of
3 each of
D13-1 qty =3
D13-3 qty =3
D13-3 qty =1
5' Pipe (2") qty =1

Yes, it would be worth a call.. I suspect if the transmissions were for saving lives and happened perhaps a few times a year, I have my doubts about them really being strict about serious fines and perhaps might turn a bind eye to it (FCC may be a little more uptight than the Canadian equivalent) I also believe there are frequencies we could use legally for this purpose. (Cheaply may be a different problem) They are definately worth talking to though. I guess the transmitters themselves being approved would be a different problem.

As a side note, I'd like to remind people that a whistle costs about 5 dollars, and a cheap water-submerisble transmitter I think could be built for 20. The transmitter would work a helluva lot better in higher winds, when accidents & problems are most likely to occour.

It seems rather ridiculous to me that some people think that $250 + dollars is an acceptable cost for what would be a technological replacement for a whistle, especially in cases where the alternative would likely be to carry only a whistle and nothing else (either due to size restrictions, or cost).

It also irritates me that government bodies may promote the loss of life by forcing all kinds of rigid requirements that drive up the costs of existing transmitters so that they are out of reach for most recreationalists, and also make it illegal to build & use less expensive transmitters, effectively prohibiting existing technology of the day from saving lives. In the end we are supposed to end up just using a whistle that really doesn't do the job and lives end up lost? Its a definate conclusion that we may end up at, but a rather ugly one.

Personaly, I wouldn't care if a small handful of people for a few minutes had to drive a few feet closer before their garage door would open. :)

Ian,
If you can use FRS radios in Canada I would go that way.
Put one in a heavy duty Zip Lock bag, with an extra Battery and a whistle &
a few glow sticks, for less than $40, probably less in larger quantities.
Those in your club that venture out more than a couple KM should spend a
little more and get Marine Band HTs.
Eric

Hello Ian

I would look at FRS radios, some of the basic ones on the market without all the bells and whistles are in your price range. They are not waterproof, so you would have to put them in another enclosure. As i recall they come in two power levels, 200mw and 500mw, and should satisfy your range requirement. A simple direction finder could use the same radio with a dipole or yagi antenna, an attenuator between the antenna and radio helps zero in on the distress signal better. You would have to agree on one of the channels to be used for emergency only. A home brew tone oscillator could be added and would easily identify the party intended to send a distress signal. Most units operate on 3 or 4 AA or AAA batteries. I would consider mounting it on the mast structure in a waterproof enclosure, use a speaker microphone - this way you could use it for normal two communication and switch it to that SPECIAL emergency channel if needed.

Just an old man thinking out loud.

Regards, Hugh

Ever drop a "waterproof" item and watch it sink the next time it's in
water?

Ever drop a radio and spend hours repairing the fractured circuit board?

Now...

Ever been sunk ten miles off the coast in 50 degree water, and found
yourself wishing you'd spent the lousy $300 on a real emergency unit
that was made to float and work after it was dropped?

> It also irritates me that government bodies may promote the loss of life by

Yeah, requirements like making it work after an impact are dumb. Any
sap floating around the hulk should be able to lift the boat to avoid
damaging the transmitter underneath, and hold it above his head while
he treads water so it will stay dry. You carry extra batteries in your
life jackets, right?

> In the end we
> are supposed to end up just using a whistle that really doesn't do the job
> and lives end up lost? Its a definate conclusion that we may end up at, but

A good emergency unit costs $300 or so. A boat costs...?

"Yeah, I got my $38,000 boat and my $1,200 GPS and my $1,200 sounder and
my $1,200 marine-band radio and my ten $150 life preservers. Why the hell
can't I get a transmitter that'll work under the absolute worst of
conditions, still float and work when the boat gets smashed, for under $20?
It has to have centimeter-accuracy GPS built in and a range of 300 miles,
with VOR/DME for the rescue planes and it has to receive DirecTV. Oh, the
battery has to last eight years in salt-water storage and still transmit
for three months when activated."

> Personaly, I wouldn't care if a small handful of people for a few minutes
> had to drive a few feet closer before their garage door would open. :)

So you don't care how it inconveniences others, as long as you get what
you want?

Yes, we would have to modify & add circuitry to it in such a way that it
could create a beacon. A beacon would enable the user to transmit
continiously, which might be difficult if the person was injured and unable
to talk or found it difficult to hold down the PTT button. Putting it in a
watertight bag may be an option, but the transmission would have to be
enabled without taking it out of the bag, as it would need to be operated by
a single person who is floating in the water, possibly injured. The end
result might be a bit bigger than what a single person would want to carry
on their lifejacket. I think if we custom made some type of transmitter,
would could get it very small. I suppose it might be possible to
dissasemble these units and use their primary circuitry & add some more
circuitry, to make them of reasonable size and provide the functionality we
need (with hopefully enough wattage).

>Most units operate on 3
>or 4 AA or AAA batteries. I would consider mounting it on the mast structure
>in a waterproof enclosure, use a speaker microphone - this way you could use it
>for normal two communication and switch it to that SPECIAL emergency channel if
>needed.

Mounting it to the mast structure doesn't help much. The most life
threatening situation is where the sailor falls off their boat, and the boat
decides to go for a ride on its own. This has actually happened, and the
sailor was somewhat hypothermic and very exhausted after the several hours
of swimming to shore, he was fortunate to have a good wetsuit, others might
not be so fortunate. Windsurfing would be a similar situation, with the
high winds potentially carrying away the board from the sailor.

Not hard to make something water-submersible, and that would sustain a
reasonable impact, quite inexpensively.

>You carry extra batteries in your life jackets, right?

Why would you need them? A single 9v battery could provide hours of
transmission, which would be plenty. (For most of our purposes, 30 minutes
would likely be sufficient)

>A good emergency unit costs $300 or so. A boat costs...?

> . . .

It's not clear to me how "government bodies" are "forcing all kinds of rigid requirements that drive up the costs" of radios. In the U.S., the only government "body" that imposes requirements on radios is the FCC. They do require that the radios don't put out spurious signals that interfere with other people's radios, aircraft navigation, cell phones, emergency communication, GPS, and the other thousands of uses of the radio spectrum. Anybody who uses any kind of radio for anything should be really, really glad that these requirements are in place. In any event, the FCC requirements probably have only a minor effect on the price of a radio, since the cost of manufacturing a radio that meets the spec is just about the same as making one that doesn't. It does take additional design work and testing, but in a volume product, that cost is spread out thin enough to not be noticeable.

If a radio costs a lot, the reason is that there's not a big enough market to make it in large volume. FRS radios are probably about the largest volume radios of their type being made, and they've settled down to the around-$40 price. Considering the competition and volume in this market, it's safe to say you just can't make a volume radio with this capability for very much less. It might be possible to make a waterproof radio for not too awfully much more, but only if they could sell a couple of million of them. Which they can't. And if you want one that's truly reliable, the manufacturer'll have to use extended temperature range and high reliability components, gold plated contacts instead of tin, and other cost-increasing measures, in addition to paying for extensive testing and quality control. That, my friend, ain't cheap, and it's not because of "government bodies". If you really think it's possible to manufacture a waterproof radio in small quantities, or in large quantities -- say nothing about reliability -- and have it compete with non-waterproof radios, for $20 or $30, then by all means you should do it. You'd have Motorla, Cobra, Radio Shack, and the others out of business in a short time. And you'll make enough money to afford a radio

that has the quality you want.

One of these FRS radios has significantly more components than what would be required to transmit a simple beacon signal on a single channel. It would be easy to make one for less than $40, I think, and one would have to be made or assembled after some fashion, to make it more durable, water submersible, and have beacon transmit capability. Still, all doable for less than 40 dollars, but possibly illegal to produce because its not FCC/IC tested. Quality & reliability are separate issues I agree, but if you are having to take out the circuitry and put it in some other type of enclosure it is already introducing quality uncertainty -- and that has to be done in any case, because no suitable product exists anywhere, or if it does, not within a reasonable price range ($300 and up).

What about an Avanche Tranciever?
They are built to withstand 200psi of snow in -30 degree weather in alot
bigger tumble than a boat will go thru!
We bury them in the snow for training and have yet to freeze one.
Sure they will cost you 150-300 bucks but like we say here in the snow
belt..."If you spend $8000.00 on a snowmobile, why the heck not spend the
extra money for some protection!"
put it in a double zip-lock baggie and voila......waterproof and floats...
I use mine year-round and go thru very few batteries...

Just A Thought...

The manufacturers are waiting eagerly for your design expertise. In the real world, you pick three from { waterproof, rugged, cheap, functional }.

If you make the case sturdy enough to protect the circuit board, the case cracks easily when you drop it. If you don't, the circuit board cracks easily when you drop the unit. OR... you use special expensive molds in expensive special molding machines and mold a special plastic, final cost $15 for the case alone (before markup).

Many (most?) semiconductor devices have only a 5G shock specification. 5G isn't much for a capsule in a kayak in rocky rapids. So you need special shock-mounting materials and design.

And waterproof doesn't always mean air-tight. If you don't have air-tight, everything -- EVERYTHING, down to the tiniest capacitor -- has to be able to withstand salt air. (Sell a freshwater rescue device, someone will use it in salt water and sue you when it breaks.) And if you do have air-tight, the battery compartment and battery have to be special.

And the battery has to work even after you've thrown it in the closet two seasons and brought it out for a third, because you're going to forget to check or replace it.

> >You carry extra batteries in your life jackets, right?
>

When's the last time you checked the batteries in your emergency devices, like UPSes, power-out lights, etc.? That's how often you'll check the gizmo in your gear bag before you get to the water and toss the gizmo into the kayak. And before you say it was less than a year, make sure you can guarantee all the buyers of this gizmo say the same, or the lawyers won't let you guarantee the gizmo will work the way you want.

You'd be aghast at the short life of a 9V battery in a 5-mile transmitting application.

So are the clothes they're wearing. Wonder how many of their $20 "waterproof" watches last an afternoon. Wonder how many kayakers spent $100 or much more on just their watches.

$500 for body piercing, $800 for tattoos, $20 for a lifesaving device.

I also wonder how many of these "kayak only" gizmos will end up in pleasure boats. So will the lawyers of the manufacturers.

> >So you don't care how it inconveniences others, as long as you get what

>
> Right, a few garage doors are less important than a human life.

A human life is valuable enough that you don't risk its continuation on a cheap rescue device. You also make sure the gizmo isn't interfering with your two-way radio, for when the rescuers get close. Anything that will shorten the range of two garage-door openers will wipe out any but the most expensive two-ways. And considering you won't spend bucks on something to save your life, I'd bet the two-way you use for idle chat isn't the best on the market.

Or you could just have a sturdy metal case, with a ciruit board inbetween some foam, and then put a bit of foam around that, and it will withstand reasonable force and dropping, we're not looking for super industrial strength units here, just something usable for average use. If all else fails you can still blow your whistle.

>And waterproof doesn't always mean air-tight. If you don't have air-tight,

It would have to be pretty much airtight.

>And the battery has to work even after you've thrown it in the closet two
>seasons and brought it out for a third, because you're going to forget to

The units would likely be tested and inspected on a monthly basis, if not more.

>When's the last time you checked the batteries in your emergency devices,

We're not selling these devices, we're making them for our own use, and the users have the option of not taking them if they so choose. They could just take a whistle if they wanted, or they could take the extra device for free, on the chance that it might offer additional safety.

>A human life is valuable enough that you don't risk its continuation on
>a cheap rescue device.

Again, the price is so expensive that these small clubs couldn't afford purchasing many of these rescue devices, in which case we would continue using only whistles (which is all we are legally required to provide).

>You also make sure the gizmo isn't interfering
>with your two-way radio, for when the rescuers get close.

I doubt a 500mw - 1 W device would interfere with a two-way radio when you got close, and if it did, what would it matter? As soon as you got to the person you'd shut off their transmitter. Sometimes, the people in the rescue boats don't even have two way radios.

They could work, but 250 units multiplied by 300 bux is 75 grand.
Definately out of the price range for a handful of non-profit small boat
sailing clubs that don't have much money. Our users are often careless
students with little money. :-) 20 to 30 bucks each is still expensive for
us, but possibly doable and may be worth the investment.

You may be interested in:

Grebenkemper, John (KI6WX). 1989. Improving and Using R-X Noise
Bridges. QST. August. 27-32, 52.

"The main cause of frequency variation of the bridge null is the
design of the transformer (T1 in Fig 1). The designs that I've seen
use a trifilar winding on a ferrite or powdered-iron toroid core.
This design introduces phase shift across the transfer secondaries at
the higher frequencies . . . .

"Both of these problems can be cured by using a ferrite binocular core
wound as shown in Fig 4. This binocular transformer directly replaces
the toroidal transformer in the bridge."

Fig 4 shows an Amidon BLN 43-2402 with 3 sets of windings, each 3
turns of #30 enameled. (The 2402 is about 1/4in high, and just over
1/4in wide, with dual "binocular" holes.) The primary leads come out
one end; both secondary windings come out the other. The two
secondaries form a center-tap by connecting one lead from one
secondary from one hole to the lead from the other secondary from the
other hole.

>right to exclude me from making, using or selling his patented item.

Not quite.

You are allowed to use whatever is in patent to carry out research on
the area that is covered. You cannot sell what you do/manufacture but
you could apply for a patent on any improvements you make. Anyone
wanting to use your patent to produce the item would invariably have to
also take out a license from the original patent. If they do not grant
one then no product can be sold.

You are not barred from manufacturing anything in a patent in order to
test that the item patented actually does behave as claimed in the
patent. This is very important in patent law! A patent has to contain
all the 'instructions' for one to duplicate the item(s) being patented.
If it is not possible to do this from the instructions or said patented
product does not work as claimed then it usually leads to a patent
challenge and has been known to lead to the throwing out of the patent
completely - via the usual court systems.

My knowledge is primarily biotechnology but the same general
observations apply to all patent law. I will be seeing a patent attorney
in the next week or two and will conform this with them.

Actually I'm not sure about the FCC, but I was quite surprised after talking with Industry Canada's director of spectrum policy and planning. He said that under no circumstances would anyone get fined or prosecuted for transmitting any kind of distress signal, radio frequency or otherwise, in a life threatening situation.

To my surprise, he suggested trying to see if it was possible to design an inexpensive transmitter in some of the less used older marine bands, and wondered if garage door frequencies or remote controlled device frequencies could be out of band enough that they may not interfere with other devices, and agreed that the FRS or CB frequencies may be too polluted with traffic to be useful for an emergency broadcast beacon. To my surprise he also encouraged creative experimentation and design of this kind of device with less emphasis as to the importance of what frequencies or wattage we may be using for this purpose.

If you can build something yourself - or get a local junior college electronics class to build as a project - a straightforward beacon should be simple. Use an off-the-shelf can oscillator, a dual 555 timer to generate a pulsed audio tone, and a single stage frequency multiplier / PA to drive a resonant coil antenna in the 350MHz region (garage door band). Power with a lithium cell or two (5-10 year shelf life). Coat the whole thing with any impervious resin and foam stuff it in an inexpensive case (35mm film can?). For turning it on and off, a magnet and reed switch or similar would be water and weather proof and take no power until used. A LED visible through the cap or even a piezoelectric bender in parallel with the modulation signal would be an indicator of transmitting.

Whole cost should be under US$20, quantity one. Range may not be many miles but can be easily measured. Give it a shot and let us know how it goes!

Jim Horn, WB9SYN/6

Finally somone helpful with good ideas. Thanks for your thoughts! Lithium batteries are a much better idea, and I agree, you might as well make these things one-offs, no need to bother making the battery replaceable.. Just toss it in the garbage if its ever been used, and test it every so often to ensure its still working. Sealing it all in some type of resin is another good idea, and put in some small case like a film-case, sure! More great ideas. Magnet or reed switch, another great idea.. No movable parts, easier to seal, reasonably indestructible.

With a resonant coil antenna, I wonder how well it would work, or for how long at a higher wattage. Any ideas of what kind of wattage we might need to put out with that kind of antenna, to get a reasonable range out of it? I was thinking it would be better to use some type of longer wire antenna, but a coil antenna sealed in the same unit would be cool if it could have enough range. I guess it may take some experimentation.

I know Hams and other people that have the means to help design the circuitry for this, so it would be a matter of perhaps gathering a team of volunteers together to help build the devices.

The primary thing I still am unsure about is what chips could we use for this? I'm not terribly familiar with all the available spectrums and chips that are available for this kind of purpose. Can garage door chips be tuned out of band enough where they are in a spot where there isn't much activity going on? What about other chips like the ones for remote controlled devices? What about chips that are used in ELT's or similar devices that are on frequencies used for a similar purpose.. Are they available anywhere and are they inexpensive?

Any suggestions or ideas on these lines of frequencies and/or chips would be REALLY helpful.

Hi!

I'm refurbishing an old Henry 2k-3 amp - I have the upper deck schematic,
but no power supply schematic. I could trace it, and work on it as is - but there
are a few parts that have been *replaced* that may or may not be appropriate
in type or value.

So, anyone who can supply:

a) emailed - scanned copy
b) emailed - PDF (best!!)
c) snail mailed photocopy
or
d) URL to one on the 'net

PLEASE EMAIL TO ME!!
I may not catch your post - since the braindead admins on this system keep only
3 days maximum worth of posts up. :- (

BTW- If you happen to have any flush mount panel meters (no cut-out needed, just for the
two meter terminals) of *any value*, let me know too - the original ones

are toasted here.
I'll have to work out a replacement/retrofit if I can't find any flush mount types)

Thanks,

_-_- bear WB2GCR

More on the do-it-yourself beacon option. The SAW (Surface Acoustic Wave) resonators used in most keyless entry systems for cars are available from DigiKey and resonate directly at the needed frequencies (my Ford uses ~315MHz). One transistor to oscillate, one to amplify; one dual 555 to beep audio modulation (or go wild - use a PIC for a buck to send a unique user ID in audio Morse code). Use a CR2477 lithium cell to power (3V, 3 watt hours). No regulator. Put the cell at the bottom of a symmetrical housing and a flexible whip at the other end - it will float with the whip out of the water. 600mW of output should last 2 or 3 hours and have a range of miles over water. A 35mm plastic film can would hold it fine and, glued shut, protect it from falls, etc. The holder for it would have a built-in magnet to keep the reed switch open - deploy it and it turns on.

The circuitry would fit on a single sided board which could be home made. Again, the cost would be under US$20 all told.

Piece of cake.

Jim Horn, WB9SYN/6 Sure beats the 6AQ5A 40M novice transmitter days (7.167MHz crystal bound - WN9DWM)

Ian,

How are you going to receive these signals, and even more importantly, how are you going to home in on one of these emergency beacons?

A lot of the value is lost when some obscure frequency that is not recognized as an International Emergency Beacon frequency for such devices, is not used. You lose the benefit of trained and equipped government and volunteer rescue groups for one.

Pete

With a directional antenna and a meter. This isn't exactly rocket science, lots of ways to do this and lots of equipment around that will do this sort of thing.

>A lot of the value is lost when some obscure frequency that

Since there is no suitable chip/frequency transmitter that is small enough, or cost effective enough, that is currently being used for this purpose, *nobody* is monitoring any type of similar emergency broadcast. At the very least, we would do our own monitoring. If it became more popular or commercialized, I suspect other government or volunteer organizations may follow. Also, for those who monitor other types of distress, such as a boat in distress, since there are many false alarms, its often hours or days before anybody does anything about it. In the case of a hypothermic swimmer near land, and not a distressed larger vessel in the middle of the ocean, this would be too little, too late.

Pretty incredible! A federal govenment official being candid, and exhibiting common sense and flexibility. Something like that could never happen in the US (no matter who is in power!)

Remember, however, that you would want to pick a frequency/band for which there would be expected to be receivers close at hand (and preferably ones capable of directional discrimination!).

>>What about an Avanche Tranciever?
>They could work, but 250 units multiplied by 300 bux is 75 grand.

Avalanche transceivers have a deliberately limited transmission range,
to make them easier to locate in an area less than 200 yards across.
They also have the receiver circuitry, which pushes up the price.
Since they are safety equipment, and the market is limited, the price
is far higher than a consumer unit of similar complexity.

For your beacons, you may want to reconsider. To build something
utterly reliable, it will be far more than $20 per unit, and your
insurance company may not like the idea of "homemade" safety
equipment. From the perspective of liability, your proposed device may
not be recommended.

No safety gear may be less liability than malfunctioning safety gear,
and you would have no reliability data to back you up. Much of the
cost of some products is not in the manufacture, but in the testing
and documentation that shows that the product is capable and reliable.
This cost is spread among all the consumers of that product, whether
there are millions of them or dozens.

FCC regs may be an issue if you deliberately build a device that
transmits on a frequency you are not authorized for. Yes, in an
emergency you can transmit any way you can. However, the implication
is that you would try frequencies you are authorized for first. You
would have no defense for a large fine for any accidental
transmissions that were not emergencies.

There is an issue of having a standard device that other rescuers can
receive and track. Standard marine or FRS radios will do everything
you want, be legal, standard and so on, except for price. In quantity
and as a nonprofit, you can probably make a deal with a manufacturer
to get a discontinued model or something for not too much more than
your budget.

Happy trails,
Gary

Personally, I agree it seems to be someone "baiting" the newsgroup. A simple (and legal) solution to this sort of problem, assuming it is a real message in the first place, is quite obvious.

Forget radio waves. Place a chemical smoke bomb, with bright orange smoke. All of the events mentioned in the original messsage would be daytime only. A smoke bomb is VERY specific to location, can be made to last an hour or so, and can be made very cheaply.

Not to mention the additional feature of not requiring batteries and / or a lot of landside technical equipment for Radio D/F locators.

Also, all of the activities listed would almost certainly be within sight of another group of people. It would be easy to set someone up as a spotter if there is some organized activity going on.

==========

They can be made in bulk, sold cheaply, and be low maintenance. For any radio beacon system to give the same probability of working, you'd need a massive tracking and battery replacement schedule.

After all, the beacon would be needed maybe once every 5 or 10 years when the boater did something stupid so that means the battery would be sitting there for 5 years or so before being used. That's a bad time to learn the battery is shot.

Besides, if someone DID build an illegal radio beacon on some unused frequency, odd's are some legal user would start using the frequency and blow all of the D/F systems to dust. Which would render the entire beacon system totally useless from that day until the end of time....

There are reasons for having certain frequencies set aside legally for emergency beacons.

==========

So, all in all, the original poster has a very simple, cheap, and legal solution here and if there really is a group that needs something like this, by all means build the smoke bomb type emergency locator.

Most metals are unsuitable to wet/humid environments. A thin enough case
will deform enough to harm the circuitry; a thick one costs, and will
still deform under the kind of stresses accidents bring. Foam rots, and
actually makes a pretty rotten shockproofing for something that needs to
be durable.

Then you're going to have to change the battery weekly. Some batteries
will last a month in an airtight case; some won't.

Is your antenna inside this airtight metal container, where nothing will
be able to hear it, or outside where it will break off at the first impact?

And you won't spill the hot coffee in your lap as you drive away, either.
That's fine for something YOU make solely for your own use. For something
you want to buy, the seller has to consider the hot coffee.

I strongly suggest you talk to your attorney before doing this. Even if
your people won't sue you, their insurance companies might. No, your
disclaimer of liability won't protect you. IANAL but I'm old enough to
have seen all too many decisions against "the good guys".

Most companies wouldn't even consider releasing such a product without
doing $20/unit in testing costs alone, if only in preparation for the
inevitable liability suits.

I suspect 500 mW (250 for the transmit power, 250 for inefficiency and
other considerations) of seawater power would require undesirably large,
heavy and/or expensive materials. Some lifeboat transmitters work off
seawater power, but they're expensive, and you wouldn't want one in your
kayak.

Uhh, no, this is not a troll, and I don't know where you get your sources of information.. But many of those smoke bombs, especially when they get wet, seem to work fairly poorly or not at all, and don't always reliably ignite. (we've tried them) Flares that shoot up in the sky have even worse performance. In strong winds smoke flares aren't very noticable from any reasonable distance, don't last very long, and somebody has to happen to be watching in that direction to see them during the minutes that they are burning, which especially at off-peak hours, is very possible that nobody is. We've concluded that they wouldn't add a hugely significant benefit in dealing with this problem.

Around here there are people out on the water 15 hours a day, and at times such as early in the morning or during a weekday, there are often very few people actually looking over the water. There have been a number of serious incidents where people have come close to loosing their life, so obviously your idea of "hope someone sees you" isn't overly intelligent. Appointing a spotter to look out with binoculars all day long isn't very realistic

either, and believe it or not, even that on a windy day with a reasonable amount of waves, you'd be surprised how hard it is to spot a lone swimmer 2 or 3 km away. Actually, we've done some experiments and its pretty much in the "next to impossible" category. In fact some of these incidents that have occoured have been in the middle of a day, on a saturday, when the bay is filled with literally hundreds of sailors, and yet even still the whistles were not heard and the swimmer not spotted, and came near to loosing his life. You'd really be amazed how easily a person can go unnoticed when they don't have a big sail attatched to them. So before you start commenting on how easy it is to casually spot a lone swimmer a few kilometers away, why not do some tests yourself to see how easy it is.

This liability stuff is bullshit. Just incorporate a non-profit
organization to produce the bloody things. Nobody is going to prove gross
neglegence to anybody who is making a safety device that works more reliably
than a smoke flare (which are currently selling on the market and aren't
reliable). Why aren't they getting the pants sued off of them? Who says we
need to buy insurance? Testing, sure, but we can do our own testing.
Caring SOME device is better than carrying NO device, no matter how bad the
quality is, and as I said its definately not hard to get the reliability
better than that of a smoke flare. Ridiculous.

We might very likely be making the recivers and directional finding
equipment ourselves as well, so picking a frequency/band for which we would
have recivers would be a given. :)

One more thing, these smoke flares are fairly fragile. They are meant to be used in a fairly large solid protective case, in such things as a sailing vessel. When worn unprotected by a number of active people on a daily basis, its VERY possible they could be damaged and rendered useless, yet we wouldn't know it. Adding protection to them would make them so large as to be unwearable on a lifejacket. These people are tossing their lifejackets around, continually submerging the flares in the water, and often hitting parts of the boat, falling off the boat, or otherwise exuding force on the flares, on a fairly regular basis.

They would need to be replaced very freqently (every few weeks)? VERY costly. We feel the risk of damage would be much less so with radio transmitters sealed in resin. Also the smoke flares are fairly large, and would be difficult and perhaps too big to attatch to a lifejacket. They really aren't intended for this kind of use, and don't work well for this kind of situation. Also I'm not sure how risky it is to let off a smoke flare a few inches from your face but I'm not sure its all that great of an idea.

>This cost is spread among all the consumers of that product, whether
>there are millions of them or dozens.

Again, we're not terribly concerned with issues of liability, and we don't have any insurance to deal with, so what would we care. The non-profit incorporation gets sued, it goes bankrupt, we start a new one. So be it. All we need to prove is that it is more reliable than no device at all, and that is sufficient. People aren't going to pay vast amounts of money for reliability testing, especially when they don't care, as they would rather have an inexpensive device that has a chance of functioning, than have none.

>FCC regs may be an issue if you deliberately build a device that
>transmits on a frequency you are not authorized for. Yes, in an
>emergency you can transmit any way you can. However, the implication
>is that you would try frequencies you are authorized for first. You
>would have no defense for a large fine for any accidental
>transmissions that were not emergencies.

FCC, perhaps, Industry Canada, may be a different story from the sounds of it. I'm getting the impression from them that if a reasonable device can be built, and if the devices can be proven to cause little interference with other devices such as car alarms and keyless entry systems (that especially being the case, since there are few keyless entry systems on the water), that it seems there is a reasonable chance of them totally approving these frequencies to be used for this purpose.

>There is an issue of having a standard device that other rescuers can
>receive and track. Standard marine or FRS radios will do everything
>you want, be legal, standard and so on, except for price.

Standard marine or FRS radios will NOT do everything these people need, and will have less reliability and applicability to the need. (if you read some other messages in the thread perhaps you would become convinced of that). In addition, there is an issue of being priced so high as not to be affordable.

>In quantity
>and as a nonprofit, you can probably make a deal with a manufacturer
>to get a discontinued model or something for not too much more than
>your budget.

and even if we did we'd end up with a bunch of fragile toys.

I've been following the discussion for a while, and I think I'd like to wade in with some comments. But, first, I should probably provide some disclaimers. All of the opinions expressed here are my own and in no way represent those of my company. Also, I'm not a lawyer, so any opinions expressed on legal issues are not to be considered legal opinions (And, of course, given that the discussion is occurring in multiple countries, the different legal systems need to be taken into account.).

On the subject of a sealed unit, sea water is one of the worst materials available for the deterioration of metals and electronic components. The salinity will cause most metals to corrode very quickly. Plus, the thermal shocks may cause the salty water to be sucked into even the tiniest crack in the housing. Couple this with the fact that the device needs to be buoyant so that it will float, which will either require an air space, or a fairly large quantity of low density material, and this may accentuate the thermal problems.

Plus, the mechanical vibrations and shocks that the device will have to withstand may tend to cause the housing to crack. And, finally, once these effects have been accounted for, there's the issue of ultraviolet light which may degrade some plastics. In other words, packaging the device is going to be a real trick. Of course, I'm not saying that it can't be done; just that it'll be difficult.

The circuit electronics will probably be the least of the design problems. One poster has already mentioned the SAW devices such as are used in remote control car access buttons. Lithium batteries are available with long shelf lives, and, by prominently date coding the device, replacement time can be specified. Of course, when designing the power source, consideration should be given to the worst case operating environment (e.g., end of shelf-life under worst storage conditions, , worst efficiency of the electronic components, maximum range, worst temperature, etc.).

Choosing a frequency may be a bit trickier, though. Several posters have already mentioned some of the concerns. You obviously want a frequency which will be relatively clear of interference for now and the future around your operating area. A safety device which is being jammed by legitimate signals won't be of much use.

Also, you want a frequency where the device won't interfere with too many other legitimate users. Interfering with one person opening their garage door is probably unimportant. Causing 25,000 garage doors to start opening and closing automatically throughout the day and night might be a bit more cause for concern. Interfering with a tower to airplane communication which results in an airplane crash might be the worst case scenario. (Ok, I'm obviously stretching it here, but I'm trying to make a point.). What I'm trying to say is that there should be frequencies which could be used for the purpose, at least, on a secondary basis, which would not inconvenience large numbers of legitimate users or interfere with

other public safety functions.

One of the choices for frequency usage may be dictated by the watery environment the device is in. If the frequency is too high (microwave bands), then water vapour may start to absorb part of the transmitted signal, lessening the range. If the device is not completely buoyant, then the sea water will attenuate the signal extremely rapidly for just about any reasonable radio frequency. However, too low of a frequency will require an excessive sized antenna for efficient radiation, and, plus, may also cause difficulties in attempting to radio-locate the source of the signal (Think of the receiving equipment and how it will be doing the radio location.).

As for the legal concerns, there are both civil and criminal issues to be concerned with. It appears that you've thought about the civil issues and are content with those. However, remember that in a civil case, the usual tactic is for the injured party to sue everyone even remotely associated with the situation. Thus, not only would the company who made the devices be sued, but the rescue team who was using the devices would probably also be sued, along with the individual team members. Thus, the damages may not be restricted to the shell company, but may be awarded from any and everyone associated.

It also appears that you've contacted the appropriate governmental agencies and have a handle on the possible criminal aspects of the radio laws. However, also consider issues such as negligent homicide and issues such as this. It's hard to believe that such a charge could arise out of the proposed use of the device, but strange things happen in the legal system.

One thing you may want to do is to search for a lawyer who would be willing to advise you on all of the legal aspects. The legal system can be quite complex at times. Given that the project is a non-profit, humanitarian based project, it may be possible to find a lawyer who would be willing to consult with you on a reduced cost or no cost basis.

In addition to the legal concerns, there may also be moral concerns. I've heard the opinion expressed that any safety device is better than no safety device, and I think everyone will, for the most part, agree with that. However, one of the moral concerns would be, if in having the safety device, that it encouraged someone to take excessive risks, due to believing that the safety device will protect them. Thus, someone may actually put their life in additional peril because of the safety device. I think we've all heard of cases where a child ties a blanket around their shoulders and jumps off of a roof, believing that the magic cape they're wearing will allow them to fly. While most reasonable adults wouldn't believe in such a magic device, there are those to whom the RF safety device will appear to be such a magic device, and may take

inordinate risks due to their erroneous belief that it will protect them in all circumstances. Unfortunately, there are a lot of idiots in this world, and at least some of them will be using the proposed device.

A weaker, but possibly more prevalent, form of the moral argument is if the new safety device causes someone to omit a previous safety device from their inventory of safety related equipment. For example, if having the RF safety device causes them to leave out a whistle, a flag, a balloon, or anything else that they might normally carry, then they may be placing themselves at increased risk.

Part of the moral and legal concerns stem from the reliability of the device. Actually, there are two scenarios which need to be considered; that of false negatives, and that of false positives.

A false negative is when a person has legitimately activated the device and it fails to function. This may be due to dead batteries, limited range, corroded circuits, lack of suitable listening equipment, masking of the signal by another signal (interference), or a whole variety of other reasons. In any case, the outcome is pretty much the same; the person's life is in danger. Thus, all of the possible failure modes must be considered.

A false positive is when the device has been triggered when the person's life is not in danger. While this at first sounds much less serious than a false negative, the consequences may be much worse. Consider, for example, that there are 1000 devices in use (I'm just pulling numbers out of the air for the purpose of this illustration, but I think it will make my point.) (Of course, 1000 people need to be present and actively using the device. Some of people may have purchased extra devices, and some of the people with the devices will have them stored somewhere. But, they'll still be present and operational.). Now, consider that, during a typical day, five percent of the devices false positive. That results in 50 false signals per day. Thus, the rescue crews have to make 50 unnecessary runs per day. How many (limited) resources are going to be expended responding to these false positives? How many of these false positives are going to be moving around, necessitating the rescue crew chasing a boat all over the harbour before it can be caught and the offending device deactivated? How long will the rescue crew be able to stay operational given such a drain on their resources?

Also, consider the case where a false positive may be interfering with a legitimate signal. Radio direction finding one clear signal is not too difficult. Radio direction finding one signal out of a dozen on the same frequency is almost impossible without some extremely complex and expensive equipment.

Thus, in addition to designing the device so that it functions when required (e.g., no false negatives), they must be designed so that they will not function when not desired (e.g., no false positives). This is going to be a very difficult design exercise. While it's impossible to prevent deliberate false positives (e.g., Some fool deliberately triggers the device just because he's bored.), accidental false positives must be severely limited (e.g., Someone tosses their lifejacket into the boat, and the shock from hitting the bottom of the boat dislodges the device and triggers it.

Some of the design issues you may want to consider would be things like having each device transmit an ID code to uniquely identify it. The problem with this is that it's going to require a custom programmed part of some type, and this is going to increase the device cost.

You may also want to consider making the devices a one-time-only type of device to discourage tampering and other sources of false positives. An added advantage is that this may require replacement of the device after a use, which could decrease the false negative situation, too (e.g., After the device has been used once, and the batteries partially depleted, the device will have to be replaced, rather than being restored to operational status with partially depleted batteries.). The disadvantage is that users are going to be reluctant to shell out the cost of a new device.

I know I've not addressed many specifics of the design, but I'm not sure that it's appropriate to address the specifics at this time yet. Before the specifics can be designed, the issues of how the device will be used need to be considered, and I think we're only beginning to address those now.

In any case, the project sounds like a worthy idea, but it's going to take a lot of work. I wish you the best of luck with it.

Dave
WA4QAL

P.S. Standard Disclaimer: I work for them, but I don't speak for them. Any ideas, comments, thoughts, or opinions expressed in this post are entirely mine, and do not have any relationship to my employer.

P.P.S. I've seen Vancouver harbour, and the coastal area there is beautiful, although there's quite a bit of shipping traffic in the harbour itself. However, the sound that's south of the city (Oh, what's the name of it? I'v forgotten it.). is even more picturesque.

Well thought out reply Dave.

The only thing I could add is that perhaps a commercial solution
may be in the works. I know some companies are working on new
man overboard devices, and there's a committee at RTCM called SC-117
maritime survivor locator devices.

There may be more info at the RTCM website at: www.rtcm.org

Let me give you an example. There are these devices that are attatched for monitoring cow feeding. They hang around a cows neck. Whenever they put their head in the feeder, there is a small radio transmission nearby that provides enough power output for the device to transmit back an identity of the cow. These devices are extremely easy and cheap to make, and are put through all kinds of abuse, being exposed to bumping, smashing into the grain feeders, continually exposed to rain and weather, worn on various cows for years. Actually I know a company locally that used to produce them, and their cost was around 10 or 15 dollars Canadian, and to my knowledge, none of them ever stopped working or broke, once proven to be working after they were hardened and sealed up. They are just plastic cases with all the electronic components sealed in a resin/epoxy like substance. Highly durable, in my opinion. Something like this could be used. Sure, maybe one in ten thousand would break every once and a while, but if we start comparing it to the durability of virtually any other electronic equipment, or even other devices such as smoke flares, there really is no comparison.

Sure, put a 2 or 3 year year shelf live on the things, that would be doable, but I think 5 to 8 years would be more realistic as to their true longevity.

Well since you can pick frequencies where users are only supposed to be transmitting 10mW or 100mW on them, and often with poor antennas, I think that isn't going to cause much of an interference. Also, since you have directional antennas, any false alarms wouldn't show up on the water. There would have to be once heck of a high wattage transmission with a good antenna on land before it would interfere. (DF find them and go beat them up!) No, the more likely scenario is that the transmission of the resuce device is interfering with the other devices.

>Also, you want a frequency where the device won't interfere with too

>other public safety functions.

The difficulty is, that the quantities of these kinds of devices that may get produced, may be in the order of a few thousand, or maybe ten thousand. I don't know how much it costs to produce those SAW chips at a specific frequency, but my guess is, to produce one at a specific unique frequency that nobody else is using except for a handful of small boaters, it is going to be pretty darn costly, for even a one time run of say, ten thousand. Thus, sharing the frequency may be a more realistic option. If anyone has any knowledge around these sorts of costs, I'm all ears to know about that too.

>One of the choices for frequency usage may be dictated by the watery

Yeah, thats why I think somewhere around 100-600 Mhz would be a pretty ideal choice, a smaller antenna, and yet not overly susceptible to interference from water or weather. Someone more experienced with this stuff might be able to give me an idea of exactly what kind of freqency would be ideal for this purpose.. (400 MHz??) I would love for more thought on that.

>As for the legal concerns, there are both civil and criminal issues

Possible. Maybe only in america. :-) I doubt something like that would happen in Cananda. The resuce team already puts themselves at a liability risk by just trying to rescue the individuals with no devices at all.

>In addition to the legal concerns, there may also be moral concerns.

When I see some of my good friends come back with hypothermia, the implication of this device being immoral is pretty disgusting.

So attatch a whistle to the device when it is sold. If they remove it on their own account, that is their problem, and we would never be held liable for that. Put a disclaimer on it, that these devices aren't 100% foolproof. However, how is it any different than someone taking out a smoke flare and deciding that now they are all protected and safe, when those things are so ineffective I certainly wouldn't trust my life to it.

>A weaker, but possibly more prevalent, form of the moral argument is
>if the new safety device causes someone to omit a previous safety

True. Many of these people, believe it or not, don't even carry *any*
safety devices (except lifejackets) because they feel they don't offer that
much beneift. (and they are right to some degree, and definately stupid to
some degree) There is some logic to it though, because if you are close
enough that someone could hear you with a whistle, it might be true that
someone can see you waving your arms about too. A more likely dangerous
scenario is where nobody can see OR hear you (windstorm, heavy rain, nobody
wants to look or go outside). I would guess that 99.9% of all these sailors
& such don't carry any safety device at all that would attract attention for
a longer range, and I think primarily for the reason that no effective
device exists.

That is a whole lot of false positives, and seems like an unreasonably high estimation to me. If it is somewhat difficult or takes a very deliberate action to activate the device, I think we would see relatively few false positives. Nobody is going to want to destroy their one-time use safety device and have to go buy a new one, so I think the number of false positives will be very low.

>Also, consider the case where a false positive may be interfering
>with a legitimate signal. Radio direction finding one clear signal
>is not too difficult. Radio direction finding one signal out of a
>dozen on the same frequency is almost impossible without some
>extremely complex and expensive equipment.

If you have two signals, then everybody is still aware that there is an emergency going on. Suddenly you attract and get everybody around to start looking out on the water for people, and perhaps several boats heading out to start searching for these numerous individuals. Once one is found, the interfering signal is shut off, and the second person then can be easily found by DF means. Sometimes just broadcasting a signal of "hey, there is someone who is distressed somewhere on the water out here" may be sufficient enough that this alone could provide significant benefit in saving lives, because you can always increase the size of your search team in case of an emergency. Also, the chances of a real emergency and a false positive, going of at the *exact* same time (within minutes) are, I think, extremly small.

>Thus, in addition to designing the device so that it functions when

Yes, the activation mechanisim would have to withstand continual forces upon it, and yet not activate, still, I don't think its that difficult of an engineering problem.

Well we probably will be including a $1 PIC chip in it anyways, but I'm not sure that an individual ID would be all that necessary.

Yes, they will definately be a one-time use device. Perhaps a two-colour LED could be used, in combination with the PIC circuitry. One colour would display that the device is still functioning and hasn't been used, another colour would display that the device has been used, but is still functioning. You should dispose of it, if it exhibits the wrong colour.

Really? Thats cool, I'll have to do some more reaserch on that. I wonder what frequencies they are using, what chips they are using, and how big the end product is.

Hello, Ian -

If you'd like, I can send you a schematic of the lithium powered SAW stabilized beacon I mentioned. Do you have any capability of making them up there? Would you like to discuss such a design? Let me know.

Best to you and your friends!

Jim Horn WB9SYN/6 Let's solve a problem, not just BS it to death folks.

Sure, know how to interpret schematics, layout and build PCB's. My biggest problem is I'm not convinced as to what chips/frequencies we should be using, but if you have a schematic for a design already I'm sure it would be helpful! I think eventually we may design something a little more sophisticated with a PIC chip perhaps.

Thanks!

I found what seems to be the only commercially available suitable device.

It, and combined with the waterproof case, sure isn't cheap, and IMO, it's still oversized.

I just turned this group on, is there a FAQ someplace?

I'm a parts scrounger, and from time to time I find a deal on a part. Is it
OK if I offer the ocassional find here for sale in this newsgroup?

Closest thing to an FAQ seems to be at
http://groups.google.com/groups?hl=en&safe=off&th=ad881aef57c63230,18&start=0&ic=1.
Unfortunately I don't think there's an r.r.a.h-specific FAQ anywhere.

> I'm a parts scrounger, and from time to time I find a deal on a part. Is it

Technically that sort of thing is supposed to go in rec.radio.swap or
misc.industry.electronics.marketplace, but that being said, it hasn't
been a problem here in the past when done on an occasional, informal
basis. I'm fine with it, but others will disagree.... it's up to your
own sense of propriety and flame tolerance. :)

Nice try, but no cigar. You inadvertently revealed yourself why this
wouldn't work!

As you pointed out, these are PASSIVE devices (similar to the anti-theft
devices used by retail stores, and the "chips" they put into domestic pets).
They only work when there is a relatively powerfully transmitter/receiver in
close proximity. They most defiinitely do not work at the distances you
would need. If you are close enough for a passive device to work, you are
close enough to throw them a life preserver!

James, I found this great little SAW device, very small, its called the
TLP434 -- what do you think of it? I think I'm gonna order one and play.
They're only about US $3 in quantity! Crazy cheap. I'm going to ask them
how much it would cost to cook me up a little batch at 243 MHz, instead of
418 or the other frequencies they have. Somehow I'm doubting it will be
real cheap. :-)

Wow, would you look at those little doodads. You could throw those in the same box that is much smaller than a cigarette pack, and it could transmit your entire GPS location to boot! Crazy. I bet they are cheap in quantity too.

You know, Richard, you've got a point there. This whole exchange must
be very trying for you. If I were you, I'd give up on us altogether,
and try one of the groups in the sci.electronics hierarchy instead.
It's clear you're in need of the kind of professional assistance that
simply can't be found here.

> Perhaps they don't require as
> much technical knowledge as they used to in the good old days.

Yep, I'll bet that's it in a nutshell. It's fortunate that you've
realized this at such an early juncture -- who knows how much more of
your time you might have wasted dealing with unqualified people?

Best of luck in your quest, and be sure to let us know how things turn
out once your problem is solved. On behalf of the group, I apologize
for our lack of insight into the true nature of your problem.

Depends where you're putting the antenna. If you use a 1/4 wave and make
sure it's at least a few wavelengths away from other objects and has a
good ground plane (nearly impossible), the book formulas apply.

You probably don't want a 1/4 wave antenna.

3787. Tayloe Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-21 08:10:19 UTC
From: bpasaric@mac.com
Message-ID: <1evch2r.1fxab551fc06aiN%bpasaric@mac.com>
Source record: 51980

How does the Tayloe Mixer work?

For the whole of my life (I am 69 now) I had to read and understand analogue electric diagrams which I can do very quickly - almost at a glance. Then, digital technology has come and is pushing out the analogous one. Now, I cannot read those new diagrams as easily as before. My brain is helplessly analogous. When reading those digital boxes I usually begin thinking of a lamp switch, which is either OFF or ON, but when the things become more complicated I lose the thread.

Now I am trying to understand how the Tayloe mixer works. Dan's description of his stream of thoughts when driving over the continent has helped me a lot, and Gerald Youngblood's additional explanation was also useful. Because I am a visual type, I have made the following picture in my mind:

We all know those situations when we watch a film or TV and when a carriage passes by, but the wheels turn very slowly forwards or even backwards. Obviously, what we see is the difference frequency between the shooting speed of the camera (25 pictures per second) and the frequency of the spokes in the wheel. First, the process is digital, because the picture is either on, or off; and so are the spokes. Second, there is no sum of frequencies, only the difference, so it is not a picture of a mixer. Third, we can see this difference frequency directly, without any additional device, like in the Tayloe Mixer. If the spoke frequency is higher than the camera frequency, the wheel turns slowly forwards (USB); and if the spoke frequency is lower than the camera frequency it turns slowly backwards (LSB). Anyhow, we see the result directly, pretty in the same way as in Tayloe Mixer when we get the SSB directly from his detector (or digital filter).

Now, will someone with a deeper insight into Tayloe Mixer tell me if my comparison and explanation are correct? Thanks.
Bozidar, 9A2HL

Hello to all.

This is not really a homebrew item, but here goes...

I have a Yaesu FT-757GX on my bench that I am fixing for a friend of mine. I got the transmit section working (original complaint), and now the receive pre-amp seems to be oscillating.The preamp works on 80 meters. On other bands- howls, S9+ noise level, and motorboating.

Any ideas, modifications, or web sites dealing with this problem would be greatly appreciated.

Thanks & 73
John N3DRA

Dan had a pretty good posting on QRP-L just last week (6/16) where he talks about the thought process that brought him to the mixer. That might help. Also, there were several threads on QRP-L in the fall of '98 around the mixer between Dan, Paul Harden and Dave Fifield. Great stuff reading the discussion between these folks.

The QRP-L archives are at http://qrp.lehigh.edu/lists/qrp-l/

Thats what I figured. A 1/2 wave at 418 MHz is 13.4", which is about right,
I think. A 1/4 wave at 243 MHz (EPIRB frequency) is 11.5", but I'm not sure
that a 1/4 antenna would be that sufficient for this application, or maybe
some extra coiling could be done to make it work better.. ??

Perhaps 418+ MHz is much more suited to this type of application. :-)

Ian & friends -

I don't have a schematic for the proposed beacon yet - I'll work it up this weekend and order the parts to verify the design. But it's not rocket science - any Amateur Extra has already verified their knowledge of how to do it. Or most electrical engineers. Unless they've forgotten.

So, anyone else want to join in the fun of creating a solution instead of bellyaching about why you cant?

More news soon. Best to all!

Jim Horn WB9SYN/6 (Anyone want to race to a proven prototype?)

3793. Re: cheap waterproof emergency transmitters?

You forgot to add "and don't let the door hit you on the ass on the way out". I thought about the solution that James Horn gave in his post. I had a SAW resonator at 315 laying around from a previous project at work so after a quick visit to the panasonic web sight, a look in the junk box, and a visit to the local Radio Shack, I built this device (I won't be needing the schematics James, but thanks) . After some tweaking I got a mile of dirty signal out of it. I'm sure with a little more tweaking and a more suitable transistor on the PA (I do strictly HF tube based stuff so I didn't have much for a solid state PA transistor for that high of frequency) I could get a couple of miles out of it. I didn't want to have such a piece of out of band dirty crap on the air for too long so I have not done any serious testing with it but it should work, all for about $20 to $25. There is also a very obvious way to to water/air proof it and and some shook resistance for pennies per unit. I really have my misgivings about the rugged part of it though. Or about getting it to last very long. A lithium battery can pack a lot of energy but if you leave it in an air tight container for hours on end in the sun I bet the inside temp will get pretty hot. I haven't done any real chemistry since college but I bet cycling from hot to cold is going to shorten the shelf life the battery long before its time.

I'd like to help Mr. Upright out but I have this thing about helping people out who get rude when told by the people he has asked to help him that he can't have the sun *and* the moon. So no schematics or constructions notes for Mr. Upright. I don't agree that he is a troll. But his manner on the NG is certainly troll like.

okay I have the one gal can and I know it gets a female connector on top.
From the connector is it a random wire into the oil or what?

Hey James.. Check this out. Holtek will cook up some of these SAW chips at 243 MHz, for a US $2000 up front fee. Crazy! I figured it would be much more than that. So building these devices using an EPIRB frequency is a definate possiblity. Now comes to the debate.. 121.5 is a little more popular for EPIRBs, and 243 is a military EPRIB, but also an acceptable frequency since some EPIRBS I know transmit on both. I think 243 would be better suited to this, since the antenna length is shorter. Ideas? I'd wager I'd have to send in my finished product to Industry Canada, but they seemed to be pretty happy about the idea of these devices existing that anyone could afford. I'm going to see what frequency they reccomend.

So I'm pretty happy, I think I've found the transmitter chip/manufacturer I was looking for, so the majority of the unsolved problems are done. :)

I think I'd want to do some experiments with their 315 Mhz variety first, and then if that went really well, we could consider producing larger quantities of these guys at 243.

So, for reference, the transmitter is at: http://www.laipac.com/msg5.htm
Now, we would need to come up with a schematic, and put in some kind of broadband amplifier to boost the power above 8 mW. :) Should be a peice of cake. Now I'm gonna have to start looking into PIC chips we could use.

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-21 19:08:39 UTC
From: Skipp <skipp@pilot.ucdavis.edu>
Message-ID: <9gtgnn$8l1$2@woodrow.ucdavis.edu>
Source record: 51995

In the gal can of mineral oil, you do the "or what" part, which is most often at least one or more resistors that equal approx 50 ohms. The center pin of your top mounted SO-239 connector is soldered to one side of the resistor(s), the can / case (ground) is connected to the other side of the resistor(s).

Above the lower HF range you might want to concern yourself with the type of path/conductors you make your resistor connections with. For best operation over a wider frequency range, one would hope to similate a path that acts like a good quality 50 ohm piece of hard line / coax right up to and including the resistor.

Heathkit did it with a rather unique sheet metal assembly that the large non inductive resistor fit into.

You must also concern yourself with the type of resistor along with it's power rating. One would hope to use non inductive types. Many home brew loads are made up with carbon and metal film resistors. Wire wound is bad news.

>don't agree that he is a troll. But his manner on the NG is certainly troll like.

Well I never imagined in coming to this group asking for help, that I would initially be treated which such incredible rudeness, or even being insulted and called a troll, for an entirely worthwhile and good project that would end up saving lives. So I'm not entirely surprised at myself for being a bit rude back to some of these individuals in this newsgroup, sorry, but I had much higher expectations than to come here and mainly just get harassed. Alas, its likely not Hams in general, just a select few that happen to hang out in this newsgroup. Also, for every 500 fantastic readers and knowledgable, helpful people, you get one who is rude and pollutes the newsgroup with stupidity.

In fact, I've never even came close to demanding the sun and the moon. All I wanted was a bit information if people knew it and wanted to give it, and creative input, if they wanted to give it. I didn't demand that anybody do anything, and I certainly wasn't asking for the sun and the moon. Mostly all I ended up getting is harassed and told that the project is a lost cause, when even government agencies think its a great idea and are offering to help me out as much as they can. Ridiculous.

So have a nice day and I obviously have little use for this newsgroup.

>because the picture is either on, or off; and so are the spokes. Second,
>there is no sum of frequencies, only the difference, so it is not a
>picture of a mixer.

Well, that is an interesting analogy. It basically seems to be a
Nyquist sampling problem, with the sampling rate being too slow to
resolve the motion of the spokes. But if we can't see the spokes at
their full rotational rate, we surely can't expect to see the sum of
sampling plus that rate. So, in my view, the experiment does not
testify that no sum frequency occurs.

Switching mixers are old (tube) technology, and bus-switch mixers work
pretty much the same way: They switch a linear signal on and off.
Balanced mixers hide the mixer frequency by switching two linear
signals which have opposite phase (or by switching a transformer
output back and forth in phase). This is much easier now that we have
small, low-cost, high-speed and matched components in an IC.

Of course, in reality, most digital logic is composed of "linear"
(analog) devices used over restricted voltage regions. As one might
expect, a large signal into the FET which is a bus switch does affect
the conduction of that switch to some extent, which is distortion.

In my view, any switching mixer *must* create both sum and difference
frequencies. (Indeed, a switching mixer *also* will create sum and
difference frequencies, with reducing amplitudes, at square wave
mixing multiples of 3x, 5x, 7x and so on.) But removing the major sum
frequency when converting to baseband has never been a problem: We
just use a simple R-C filter, or even amplify just audio. We can and
sometimes do listen to AM signals with a zero-beat BFO. Nobody is
concerned about the double IF frequency produced by the product
detector.

The real problem has always been that this is not a "single signal"
system, in that signals slightly above the mixing frequency convert to
audio (baseband) just like signals slightly below the mixing

frequency. So it works for AM or DSB, but not so well for SSB or CW.

Now, if we have a pair of mixers in quadrature, with appropriate fixed-phase quadrature signal delays, it is possible to reject one mixing sideband, to some extent (up to 30dB or, with another stage, perhaps 50dB). This is also well-known old technology (and we really want 100+dB). Unfortunately, the necessary fixed-phase delay at audio has always been both a problem and a limiting factor in performance. But I don't see that as having been fixed, or, indeed, affected at all.

>Third, we can see this difference frequency
>directly, without any additional device, like in the Tayloe Mixer. If
>the spoke frequency is higher than the camera frequency, the wheel turns

>result directly,
> pretty in the same way as in Tayloe Mixer when we
>get the SSB directly from his detector (or digital filter).

That sounds like the real problem, displayed: We can "see" spokes equally well both at slightly above, and also slightly below, the mixing frequency. In fact, if the shot lasts long enough, we can go through a couple of these, as the wheels speed up. I think I have actually seen cowboy movies where the stagecoach uses larger and smaller wheels, where one can see the spokes of different wheels rotate in opposite directions simultaneously.

>Now, will someone with a deeper insight into Tayloe Mixer tell me if
>my comparison and explanation are correct? Thanks.

Hello, I have two old IC-22S's with mods. One works, the other one doesn't. They have had 42 position switches installed and toggles switches added to the front and a small circuit board installed inside. The two rigs have different circuit boards and wiring inside. Looking at old ads in ham magazines the mod could have been a Valley Instrument Products VIP-42 kit. So does anyone have info on mods that somewhat fits the decription I have given? Would a copy in some form be available. I'd really like to get the none working rig going.

Bozidar,
Your analogy sounds like a very good description to me but Dan would be better at confirming it. Another way of thinking of it is that when the carrier is at zero beat the in-phase side of the detector will integrate 0 deg and 180 degree segments of a cosine wave which adds to zero through the differential inputs of the op amp. When you offset the carrier either way it will no longer add to zero but will be a wave which corresponds to the difference frequency. If you think about the sum frequency which is the same as 2X the carrier frequency you will have two complete cycles of which also add to zero. In other words with perfect components even harmonics add to zero in the output of the detector.

For those who do think digital, this looks a lot like a comb filter where it responds to odd harmonics of the carrier frequency. By the way you only need a roofing filter with this detector to get rid of the harmonics. My measured output from the detector looks like this with no input filter:

7.1591 MHz 0 dB
7.16385 MHz -3 dB
7.16743 MHz -6 dB
7.21065 MHz -20 dB
7.61212 MHz -50 dB

If I did my math correctly that is a 9.5 KHz bandpass and a Q of 753. I can reduce the bandpass simply by changing the sampling capacitor value.

73 to all,
Gerald, AC5OG

3811. Re: Tayloe Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-22 13:11:26 UTC
From: Dan Tayloe <dtayloe@home.com>
Message-ID: <3B3343FD.12B2BCC7@home.com>
Source record: 51908

Actually I think the wagon wheel analogy is the same effect. You can tell from the apparent direction of the wheel whether the it was faster (moving forward) or slower (moving backwards) than the motionless state, which is exactly in sync.

The same effect is used to determine if a signal is LSB (slower than zero beat) or USB (faster than zero beat). Looking at just the 0 degree ("I" for "In Phase") and 90 degree ("Q" for "Quadrature") components, "I" leads "Q" by 90 degrees on one side of the carrier, and "Q" leads "I" on the other side.

Thinking about the wagon wheel analogy to USB/LSB, I think I leading Q is USB (wheel moving forward, frequency higher than zero beat), and Q leading I is LSB (wheel moving backward, frequency lower than zero beat).

What the phase shifting network does is delay one side by an extra 90 degrees more than the other side. Suppose we shift "Q" by an extra 90 degrees compared to I.

On USB, I leads Q by 90 degrees, now adding phase shift, I leads Q by 180 degrees.

On LSB, where Q leads I by 90 degrees, add the phase shift and now I and Q are both in phase.

If you sum the two sides together after phase shifting, LSB signals will add from I and Q, but USB signals will cancel (180 degree signals are negatives of each other).

Alternatively, if you use an op-amp to differentially sum the two together, the 180 degree apart USB signals will now add together, and the same phase LSB signals will now cancel.

Take your pick. USB or LSB depending on how they are put together.

On the other hand, if you used a Tayloe detector, just running the detector clocking backwards will also switch the sidebands, which may be simpler.

3812. C rowbar Circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-22 15:14:01 UTC
From: GaryH <garyhendricks@hotmail.com>
Message-ID: <obJY6.22823$9r1.1940559@e3500-atl1.usenetserver.com>
Source record: 51909

I have built a 40 amp DC supply to run my transceiver. I need
a crowbar circuit for OVP. Does anyone sell a completed or
kit crowbar circuit? I don't have time to scrounge parts for one.

Thanks

Thanks for reading this message. I am clearing my Ham Shack of dormant projects.

1) BIG PLATE TRANSFORMER, looks like tape wound Hipersil core. 230ac pri &
4400vac sec. This transformer sags quite a bit? Secondary would with #18 ga. wire? weights approx. 80 or 90 lbs make offer

2) LARGE Filter Capacitor array. 15 caps 1500mf @ 450vdc, 100mf @ 6750vdc
mounted on a fiberglass board with eq. resistors and bypass caps. $100.00

3) 4-10000A.....two were sold a good by k3lr $250.00. two were hamfest
$25 ea.

4) TWO Eimac chimneys & sockets for 4-1000A or 3-1000A Still checking for
my check stubs on cost, but make reasonable offer?

5) HEAVY DUTY FILAMENT Transformer 7.5VAC center tapped. NIB, must be 20KV
isolation between windings. $100.00

6) Small rotary inductor for input network. (pair of 4-1000A) porcelain and
very high quality, 24UH. $25

7) LOOKS LIKE 6 meter conversion, SB-2000AS commercial AMP. Uses pair of 3-500 tubes. Tubes not included. Have original print. Case good & power supply OK. $250.00 plus shipping

8) TWO Dentron DRT-2000 PLATE TRANSFORMERS with filter caps. $150.00

Send reply or call (419) 589-6196

Thanks

Dennis, w8nw

I'm intersted in this also, as I sold such a PS to a good friend and
we want to build a crowbar for it. If what I read in the 1998
handbook, it simply shorts out the supplu so the fuse blows. Yah?

It just has to feel really great to say "Tayloe detector", knowing the
name is really deserved. I know it's way different from how it feels when
I say "Sharp television". :)

If you're only concern is over voltage, get a large zener rated
for whatever voltage you want and put it across the output. If
you want to be a bit more elegant, use a small zener rated right
at the output voltage and use it to trigger an SCR connected
across the output.

However, I'm against crowbar circuits in the first place. IMO, a
better solution is using a zener to detect over voltage and then
disconnect the ac input. Much nicer and no big bangs. :-)

I built one with a scr (about 75 amps or so) and a 15 volt zener diode....the diode goes in between the trigger of the scr and the output of the power supply. the clamping ends go across the filter capacitor. I used to have the clamp across the output of the power supply but when it would fire, it would sooner or later pull out one or more of the pass transistors. To keep the crowbar from getting too sensitive, I also installed a small capacity (4000 mfd's or so) across the output of the power supply...otherwise minor glitches would cause the crowbar to fire.

> you think I was describing?

Ummm. If you completely pot the circuit (like your examples), you have a nice ocean-proof package, but you have concurrently eliminated any means of battery replacement, conventional switching, and external antenna attachment. That's why the cow-transponders work so nicely, they don't require any external attachments because they're passive!

Your lack of understanding this fundamental problem would make me question your ability to judge the brightness of others. Try not to piss off the people you are seeking help from!

Sounds like a great project that I'd like to be involved with, but not with someone with your attitude. Hope you get what you want from the more patient members of this newsgroup. You've squashed my interest. Bye.

That's the most common, reliable & simplest way of doing it, you'll find that method used on a lot of bought psu's, it's simple, quick and reliable. So what if you do blow the psu if it ever gets triggered ? ... the main concern is usually with the equipment on the output of the psu, not the psu itself.

Instead of using an SCR to short the output, you could always use a relay/output switch of some kind in series with the output to open in over voltage state but mechanical relays take time to open although only normally milliseconds it could be enough to blow whatevers connected to the output, it depends.

If you want the circuit diagram for the basic SCR crowbar i'll send it.

>However, I'm against crowbar circuits in the first place. IMO, a
>better solution is using a zener to detect over voltage and then

As someone else has stated, the smoothing caps can hold quite a charge thus continue to provide power for a short while (depends on there load).

Also disconnecting the ac input does stop over voltage on the output at the onset of a psu fault.

Using series devices is not as reliable as shunt devices, what if the series transistor goes short in the process ?

You could always cascade - 2 or more separate circuits series i guess but shunt would be better. Semiconductors tend to go short (from experience) rather than open circuit but nothing can be 100% guaranteed :(

When the supply goes to overvoltage it is usually because the pass
transistors have shorted and when that hapens teh current foldback will
not work.

I have current limit designed into this power supply. I will fold back
if 45 amps current is drawn. The crowbar should put supply into
overcurrent limit and not blow it up. Thanks for all the replies
but it looks like I am going to have to find the parts since I don't have
anything in the junkbox that will work. Those minimum orders to get
parts make these projects a lot more difficult than in the past.

Source record: 51926

The "big filter caps" shouldn't be discharged if everything is
designed and incorporated correctly--indeed, the caps should
remain charged. Most decent supplies are current limited, and
if the crowbar trips, the supply should go into a fold-back condition.
If all else fails, a supply line fuse should be between the crowbar
and supply side as further protection.

Relying on a relay (or SS triac switch) to trip the AC side will allow the
full energy
of the filter caps time to discharge into the load--your rig on
overvoltage... By the time the dust settles the semis will be
toast. There should be no bangs, arcs or snaps if everything
is done properly.

Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew

My father-in-law (W9OIB) wants to install his old BUD variable low-pass filter (model LF-601-A) at his station. When I put it in, the SWR was so bad that his TS-450S could not tune it up.

The unit has 5 adjustable capacitors (A, B, C, D, E from Input to Output). They are labeled as follows:

A - Variable impedance
B - 2-3-4
C - 4-5-6
D - Variable Impedance
E - Variable Impedance

For test equipment, I have an Autek SWR analyzer, a sweep generator, and a dual-channel oscilloscope.

Does anyone have a manual for this filter or a tune up procedure. I would gladly pay postage and copying costs for a manual.

Thanks
Ed Bailen - N5KZW

3834. RF Pulse Generator Use and Manual

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-23 14:38:56 UTC
From: n5kzw@arrl.net

Source record: 51931
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew

In the junk yard the other day, I came across a Kay 5070-B Rada-Pulser Sr. RF pulse generator. It was only $3 and I figured the switched attenuator was worth that much at least.

When I got it home, it only took about 15 minutes of tweaking to get it working right. I searched on the web and found a manual for $23, but given that I only paid $3 for the unit, I'll pass at that price.

Does anyone out there have a manual they might be willing to copy? I'll gladly pay copying costs and postage (up to $6).

Second question: what neat things can one do with an RF pulse generator? (Aside for checking for impedance discontinuities in a length of cable?)

Thanks,
Ed Bailen - N5KZW

modulating a pair of 813's with 811's. Is it possible to do this safely
(transformers sake) if there is 2000vdc on the 813's and 1200Vdc on the 811's?
Other ramifications???
Thanks

Ed, something wrong if you can`t get a 10 meter signal through a LP filter...they are designed to" cut off " at about 40 mhz. anything beloe 40 mhz should go through.. with the scope ,sweep gen and a 50 ohm load you should be able to trim the filter to reject any signal above 40 mhz...try putting sweep gen to filter input, set gen to sweep from ,say 35 to 45 mhz.connect scope and 50 ohm load to filter output..set gen and scope to read about 1 volt pp..you should then be able to tune filter to pass all below 40 mhz and attenuate all above 40 mhz..anyway this is a starting place .with a bit of practice you should do OK.. if you can open the filter take alook see about lightning damage etc..look for open and shorts.. good luck Harold W4PQW

Hi All,
I would like to reduce the moderate AC hum I do hear in the headphones
especially when I tune the bands searching for weak CW sisgnals.
Do you have any suggestion on how to block or reduce the hum without
buying an expensive DSP digital filter ?
Tnx for any possible help.

Many of the Astron supplies would crowbar on noise--a real problem
when you are using their 50RSM models in repeater service.
Astron used a small value cap right across the gate and ground--
usually increasing the gate capacitor to .47 uf or so stopped
the false triggers.

Hi Mark

Well I'll be....

The RA1772 RX was one of the last model numbers I had expected to see in the news
groups...

I repair these (as well as the TA1860 TX) on a daily basis. I work for a company that maintains our defence force's HF equipment.

Anyway..
It was a pleasant surprise to see your posting.

>73, Bill W7TI

You're missing a key concept; the crowbar removes the overvoltage from the device connected to the power supply (by shorting the output). Snapping off the AC feed, no matter how quickly you get it done, may not save your connected device from being "done in" by the energy stored in the filter capacitor.

The slickist system I've encountered put a regular 3AG fuse, rated for 2X the supplies legitimate output, between the filter cap and the regulator. In the event of a regulator short-out and a crowbar trip, the middle of the fuse does disappear with a pop, but that's really pretty tame, because the output power disappears without the necessity of emptying the filter cap. With larger supplies, it gets hard to find SCRs big enough that the filter cap can't destroy them.

Hi Peter,

No chance of an "in" on those TA1860 RX's is there? :)) More to the point....
how do I get my hands on a few of the matching amplifiers? Now that WOULD make
an really interesting ham station. Quality RX and loud with it!! I have just
acquired another 1772 and if I don't sell it at the local hamfest later today it
will appear on eBay tomorrow night. How do you rate them being a professional?

73 for now

Mark

John,
To get good second harmonic suppression you have to have good clock symmetry. I did not in the test that I did earlier. I plan to correct that in my future layout.

With poor symmetry I got:

14.318 MHz -26 dB (This should be down >40 dB with a good clock)
21.4782 MHz -13 dB
28.6369 MHz -31 dB
50.111 MHz -25 dB

What you need with the Tayloe Detector is a simple low pass filter rather than a band pass filter. The detector itself is a narrow band pass filter you do have to get rid of the harmonics.

73,
Gerald, AC5OG

Hello Gerald

Thanks for the excellent post. I like the description of it being a comb filter - slowly it is starting to make sense to me. The implications of it being sensitive to odd harmonics are that front-end filters will be necessary, possibly a little wider than octave filters if they have steep roll-offs. I was begining to think that the Tayloe Mixer with no front end filtering might be a little too good to be true.

Would it be possible for you to do some measurements around the second and third harmonics of the fundamental frequency, ie around 14.3 and 21.45 MHz, and then post them? This would be helpful to me and no doubt others to understand this mixer.

Thanks and 73

John KC0GGH

On 2001/06/21 you posted:
<<Bozidar,
Your analogy sounds like a very good description to me but Dan would be better at confirming it. Another way of thinking of it is that when the carrier is at zero beat the in-phase side of the detector will integrate 0

deg and 180 degree segments of a cosine wave which adds to zero through the differential inputs of the op amp. When you offset the carrier either way it will no longer add to zero but will be a wave which corresponds to the difference frequency. If you think about the sum frequency which is the same as 2X the carrier frequency you will have two complete cycles of which also add to zero. In other words with perfect components even harmonics add to zero in the output of the detector.

For those who do think digital, this looks a lot like a comb filter where it responds to odd harmonics of the carrier frequency. By the way you only need a roofing filter with this detector to get rid of the harmonics. My measured output from the detector looks like this with no input filter:

7.1591 MHz 0 dB
7.16385 MHz -3 dB
7.16743 MHz -6 dB
7.21065 MHz -20 dB
7.61212 MHz -50 dB

If I did my math correctly that is a 9.5 KHz bandpass and a Q of 753. I can reduce the bandpass simply by changing the sampling capacitor value.

73 to all,
Gerald, AC5OG >>

Gerald, I am confused. I was under the impression that the Tayloe detector output was dc to audio output with the bandwidth set by the .47 microfarad caps. The harmonics of the local osc. should be of little concern. Am I missing something?

Ralph

Yes, odd order harmonics will pass. You can demonstrate this for yourself simply by sketching a few pictures.

At the fundamental, draw one full cycle of a sinewave and break it up into four pieces.
You will be able to see the third and four areas (180 degrees and 270 degrees) are simply the inverse of the first two (0 degrees and 90 degrees).

Remember, 0 will be differentially summed with 180 to get a single 0 degree ("I") signal, whereas 90 will be differentially summed with 270 degrees to get a single 90 degree ("Q") signal.

Remember also that these RF quarter section pulses are being **averaged** onto a detector cap via the system impedance, each of those four areas ends up with the average (integral) of the RF pulse over that quarter section area.

Now draw two cycles of sinewaves and break them equally into four pieces. You will notice that 0 and 180 now look the same and 90 and 270 degrees also look the same. When the averages of these four areas are differentially summed together (0&180, 90&270), they will cancel. This will happen will all even harmonics. The degree of cancellation depends on the balance of the circuit. At one time I measured this at 40 db down. I do not remember what circuit configuration that was.

Now draw three cycles of sinewaves and break them into four pieces. Each of the four pieces will have 3/4 of a sinewave in it. If the 0 degree piece averages to be a bit on the positive side, the 180 piece will average a bit on the negative side and thus there will be some net detection. The same happens on the 90 and 270 degree sections. There will be some net detection. I think I measured something like 12 db down at the third harmonic.

On higher order odd harmonics, each 1/4 section will see a longer and longer sinewave pattern, most of which averages to zero, but there will always be a leftover portion that will be non zero, and will differentially add with its companion detection output. You could actually do the math (take the integral of the sinewave sequence and calculate the average over that 1/4 section) and determine how far down each harmonic should be from the peak.

If you do the integration for the straight fundamental case, you should be able to derive the 0.9x detection, which is also 0.9 db of loss (integrate over +/- 1/8 cycle either side of the sinewave peak).

Fully and completely aware of the problem, but don't think its a problem at all. :)

>Try not to piss off the people you are seeking help from!

Sorry, I do apologize for being a rather harsh for my comments directed towards you, when they should have been directed to a message I read just prior to that, and I guess my boiling point had runneth over. I became TERRIBLY offended by that message, some of the others, as well as other moderately offensive messages I had recieved personally by email prior to that, I was pretty pissed off at the whole group in general (and almost rather I hadn't even bothered to post here in the first place), I don't need to be offended when I'm here just looking for technical tips and creative ideas, so thus, I have little use for a group of people that have offended me -- I can easily find the help I need elsewhere from people who are less hostile and offensive, more open minded, with a more creative and positive attitude. In fact, you'd be surprised how helpful, professional, and open minded the folks have been in the sci.electroncis newsgroups.

>> >In addition to the legal concerns, there may also be moral concerns.

>while they play."

So when someone comes by and has so little disregard for human life, ANY life, be it me, my friends, people I don't even know who may be using a device similar to this, and they come off insulting and offending me for it, well, you can understand how I would be a little irate to say the least. When I came to ask for help, I sure didn't ask for this bullshit. This guy has got to be one of the biggest discraceful peices of human flesh I think I've ever come accross.

73, Ian

Hi,

I'm try to locate a source for a MC145151- a Motorola synthersiser part (prog divider, phase comp etc.). The part is no longer make and searches of the Web haven't turned up a stockist.

Any one know of a stockist that isn't on the Web. Prefer in UK, as postage from US tends to swap the cost!!!!

Ralph,
I think the reference to 3rd harmonic responses means that the circuit will theoretically detect signals at odd harmonics of the LO sampling frequency. In practice, there are also responses to signals at all harmonics of the sampling frequency. The magnitude of these responses is a function of the order of the harmonic, and heavily favors the odd harmonics. This just points out the need for an RF input filter, but this filter can be somewhat 'sloppy' compared to image-reject filters required for heterodyne receivers.

What's really cool about Dan's circuit is that everything for a phasing type DC receiver, up to the audio phase shift network, can be integrated on one chip. Historically, the audio phase shift circuit has been the most troublesome part of a phasing receiver, but modern DSP technology makes it possible to implement that part with extremely high precision and very low component complexity. With DSP, software can be implemented to automatically compensate for phase and amplitude imbalances in the hardware.

I think Dan's technique, combined with DSP I/Q audio processing, will make it possible to build very inexpensive & high-performance multi-band radios. I'd like to hear about some experimentation along these lines.

For UHF, the antenna would be short, rather non-critical in
length, so you might consider potting the radiating element
into the package as well. There are so many external influences
at play on your antenna that potting it will make very little difference.

Hi Gary,

One thing to consider - The crowbar should only be needed when something breaks. Generally the regulator IC's are not what goes. Most of the time the thing that goes in a power supply is a pass transistor. Once they go (shorted usually) your current limit goes at the same time. Since you have no control over the pass transistor you can't do current limit ....

To truly give you safety the crowbar has to be big enough to blow a fuse somewhere in the circuit. At low voltages fuses can be a voltage drop that you may want to avoid, but their isn't a lot of choice. Fuses have a rating in terms of the maximum number of amps they will dump into a load during short circuit. Often it's an amazing number of thousands of amps. The SCR or what ever needs to be rated for the same amazing large number of amps on a single hit / short duration basis. This is a different rating than the devices continuous current rating and fortunately much larger. Multiple thousand amp SCR's can get a bit large :)

Circuit wise it's a pretty easy circuit. The anode of the SCR goes to B+ and the cathode to ground. The gate goes to ground through a 100 ohm or so resistor. A 15 volt zeiner in series with a 100 ohm resistor goes from the gate to B+. The cathode end of the zeiner goes towards B+. The crowbar should trigger around 16 to 17 volts. That's high enough to avoid false trips, low enough to protect the radio. If you have trouble with false hits put a 0.01 microfarad ceramic cap from gate to ground. If you fuse your supply with a normal 50 amp fuse then you probably will need an SCR rated at a couple of hundred amps on a continuous basis. You will probably get away without a heatsink on the SCR.

Hope this helps.

Thanks Joe for clearing up my confusion. An input filter could reduce any harmonic radiation from the mixer as well. I would think that the I/Q and DSP portions of the new cellphone chips could be used to complete the design of the receiver you suggested.

I find it also helps to add a resistor from the 100R resistor (not gate side) to ground (say 10K) just to keep the gate from floating around which can be another source of false trips (apart from spikes).

It would certainly be interesting to try, but other experts have given me the opinion that having a longer wire antenna could make a pretty significant difference as to how much further distance could be achieved. Other opinions on this??

Thus, I was envisioning an epoxy sealed device with a little cover over it, which would also have a water-resistant seal. The cover would just hide the anntenna and keep it from getting wet or damaged. The lid, in fact, could have a magnet epoxied on the inside of it, and when the lid is extended around and inverted to fit on the bottom of the device, it would become activated. Both the lid and the container would have holes in them so a string or rope could be attached, so the lid & cover are kept together, and the device could be worn around your neck or tied to your lifejacket somehow. Little small plastic containers with a water-resistant seal exactly like this are readily available without any modifications.

I thought I saw an article on this very subject in a current magazine on the news-stand. I will go and see if I find it again, but it does stand in my memory as a June 2001 magazine.

I've done some work on measuring them as sources of interference on a 2.4 GHz spread spectrum radio my company was building and they are indeed rather unstable in terms of frequency so I think I will go and find that article just to see if they have some way to make them stable enough to be useful.

Hi,

The basic problem is that the gizmo in the microwave oven is a multiple cavity magnetron. Each cavity runs more or less at it's own frequency. The cavities are not super high Q and they each wander around a bit. This makes for a fairly broad spectrum out of the tube. You can do a very nasty sounding CW transmitter with them or some pretty rough FM / AM (you get both at once ....). All this assumes that occupying an entire band for one QSO is not a problem.

To clean them up you use a phase locked loop. You can modulate the supply voltage or the magnetic field. Since they generally use permanent magnets you are stuck with modulating the supply voltage. If you can modulate the supply out to a couple of MHz and run a quiet enough source into the other side of your phase detector you can quiet them down some. You will probably have to swing the supply at least +/- 10% to get the job done.

If you are doing all this on a radar tube that was designed for a fairly low noise output the chances of success are pretty good. With an oven tube quiet was never ever part of the design. The matching between the cavities may not be close enough for you to quiet things down. I would not count on getting it to work with the first tube I tried. Plan on five or ten tubes and you'll be in the right ballpark.

After the noise is taken off the source you can do AM, FM or CW. Depending upon which one you go for you may need to do a little fiddling with the phase locked loop and/or your reference source.

Once you have the source quieted down then you have a power source without a connector on it. Most modern microwave oven tubes just sit in a simple sheet metal box. Not much worry about polarization when you're cooking chicken :) Generally the approach is to get out the milling machine and design a transition to what ever you are going to use to move the power. If it's waveguide you go one way if it's coax and connectors you go another way.

Unless you really need the KW level of power it's a pretty complicated and expensive way to go. It's a *lot* cheaper to get on with other stuff and a lot less hassle to get it all running right. There was some stuff at the last Hamfest I went to that would do it for 1/4 the cost, assuming that you would be happy with 200 watts and didn't need 750 or more.

Enjoy!

Joe,
The design you describe below with the Tayloe Detector directly driving a PC sound card for DSP is exactly what I am building. I am using Visual Basic, DirectX8 and the Intel Signal Processing Library. I have it working now using FFT fast convolution filtering. I don't have the I & Q balancing yet but I know generally how to do it. You can't beat this design for simplicity, low cost, and performance from what I have seen so far.
73,
Gerald

There is a simple crowbar circuit in the homebrew -> power supply area
of my homepage (below). Also, Lambda (power supply mfgr) had crowbar
"modules" for various voltages (have one for 5.x volts). Don't know
about current product line.

Source record: 51868

I currently have for sale a nice copy of "Radio Fundamentals" by Arthur Lemuel Albert, published in 1948 by McGraw-Hill, first edition. The 595 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Dark green cloth covers with gold lettering on the spine. The book covers the basic acoustical and electrical principles of radio. A nice old text. Available for $10 plus $2.50 postage (book rate within the US). If interested, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

Dave

3872. Re: cheap waterproof emergency transmitters?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-25 04:39:54 UTC
From: Jimbo the Clown <james@xicom.com.au>

Source record: 51869

To make best use of existing facilities, why not target the VHF marine allocation? No one could whinge about the use of these frequencies for marine distress purposes, and every second boat has a transceiver.

Here in Aus, you could use channel 67 (the secondary distress channel, thus away from the bulk of calling traffic) at 156.375MHz.
From tried-and-true foxhunting experience...

Build a single transistor oscillator, using a 12MHz crystal. Force the crystal off frequency by 28KHz with some (adjustable) shunt/series capacitance. Capacitively couple the output to a tank circuit and antenna resonant at 156.375MHz (using the oscillators' 13th harmonic).

Aye, the power and efficiency is fairly lame, but we'd hunt these (144MHz) oscillators over several kilometers of bushland using a handheld transciever and a 2-el quad or 3-el yagi. A crystal-stability transmitter with one transistor!
If you were enthusiastic, a gain stage or some formal multiplication (with a step recovery diode or a varactor) would no doubt improve the circuit out of sight. Modulate the crystal pulling capacitance (with a varactor) or the supply rail with a pulsed square wave (ie 2 x 555 timers or a single 556 device), and now you've got a...

crystal controlled transmitter,
with a current consumption of <5mA,
cost of ~A$10 (excl. battery),
volume of less than a matchbox,
a distinctive tone
and able to be picked up on any VHF marine set!

Now you can make some directional antennas, get an exact crystal cut etc etc etc...

Cheers,
James VK2XQF

3873. HV Fuse Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-25 05:37:19 UTC
From: Bob Dodson <wb5apd@alltel.net>
Message-ID: <3B36CE0F.CA34F3E9@alltel.net>
Source record: 51870

I have an amp here with a special fuse in the positive HV lead. The HV
is +3600 vdc.
The fuse is a special 1 3/4" long fuse that has been taken apart and
filled with powdered silica.
My question is can I replace this with the shorter 1 1/4" CERAMIC fuses
that are available here in USA. These 1 3/4" long fuses are made in
Russia and hard to get plus the have to fill them with silica thing.
I want to keep the fuse inline. I have magnetic breakers on the xfr
primary BUT I have had some tube flashovers and the HV fuse blew but
zero damage to the HV diodes or anything else. In fact I have had more
than 1 flashover with some new tubes till the vacuum is reformed and the
internal gold particles or whatever has done it thing. The fuse really
works well to protect everything. The one in there now other than being
longer and filled with silica is normal fuse size in dia..
I know folks say to never put a fuse in the HV line but I really think
I would have blown the diode string if not for the fuse.

A high voltage fuse has some special requirements, notably it must break without sustaining an arc. If an arc forms, the fuse might as well not be there. That's why it's longer and is filled with insulating material that has a higher breakdown than air.

I would replace it with the right part. An alternative would be a series string of fuses that add up to the sustaining voltage.

Contact Bussman or Littelfuse, for example, for suggestions.

I've missed some posts about this after being out of town.

Perhaps somebody has already suggested this but in Silicon Valley they're selling FRS transceivers for as little as $15 each without the PL capability. For the price that's a pretty cheap radio and it's hardly worth trying to build something. How about adapting them? Over water they should provide something near their claimed 2 mile range if the antenna is at all above water. I have a pair that I paid $20 each for about a year ago and the battery life is very good. Even my wife dropping one hasn't put it out of commission.

???

Message-ID: <3B37128B.ECA8566D@dialpoint.net>
Source record: 51875

The other Bob gave good advice. Fuses have three ratings that ate
important. The normal current rating you see, the voltage rating and
the maximum current rating. Most fuses in America you see are 32 volt
fuses, 250 and 600 volt fuses. This is the maximum voltage and you can
use the higher voltage fuse on lower voltages without a problem. As Bob
said you can get an arc just as as arc welder and the fuse acts as if it
has not blown. The maximum current interrupting rating works the same
way. This is usually in the many thousands of amps. I am not sure what
is in the fuse but it is there to prevent the arc from forming when the
fuse blows at the very high voltage. You should see the fuse where I
work that is in the control voltage side of a circuit. It is only rated
for 1/2 amp but the voltage is 5000 volts. The thing is over an inch in
diameter and about 10 inches long.

Gerald,
Sounds like you're doing exactly what I've been hoping someone would do. I'm surprised that no one has used a PC sound card before to do the I-Q processing.
I travel a lot, and I've often thought it would be nice to have an extremely small, low power, multi-band radio I can just stuff into a corner of my bag. Since my laptop goes wherever I go, it would be a natural to use it as the DSP processor, audio amp, and front panel for a full-featured rig.

Please keep me and the group informed....this is ground-breaking stuff.

3879. G3sek Screen Regulator Board Mods

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-25 13:21:21 UTC
From: willy <willyacht@yahoo.com>
Message-ID: <8GGZ6.2013$e5.10811@newsfeeds.bigpond.com>
Source record: 51876

Anybody modified this board for higher screen currents? I want to mod this board to handle 2 Russian Tetrodes. Any suggestion on what has to be upgraded? Its current range seems to be limited despite what the advertising says about handling 2 tubes.

Will

3880. Re: HV Fuse Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-25 13:29:05 UTC
From: Dan Tayloe <dtayloe@home.com>
Message-ID: <3B373C9D.FA231439@home.com>
Source record: 51877

Many years ago I used to help a friend build a bunch of home brew amplifiers and we always used the normal 125v fuses in line with the HV.

Effective? Yes. Safe? That was another matter. When we would get a short in our 3000v line, the metal in the fuse would blow as expected, but it simply turned into a conductive plasma gas. The current kept flowing. The plasma in turn would then get super heated, expand, and blow the fuse body into glass dust with a sound like cherry bomb. That stopped the current.

It works, but that was back in the days when I really could not afford any better.

Sounds distinctly like an HRC fuse.

Try a small resistor from each cathode to ground.
I normally use 1 ohm at .5 watt.
They seem to snap around 1 amp.
Saves the PS and shows which tube ranaway.
Can put it in place of HV fuse if you want.

Or - Put a normal fuse at each cathode...

Hell, you can get them for FREE! They are all over obsolete and
obsolescent printed circuit boards that are tossed out every day.
Old 1200/2400/3600 bps modes, old mainframe and min-computer
circuit boards, old consumer electronics..... etc., usw.

Usually the folks with the ability, moxie, and inclination to
solder them *into* a circuit, will bother to apply the same skills
to removing them *from* a circuit.

Hey, go for it!

It's a free country. Personally to me, it's cheaper to pay a few cents for brand new ones than to spend my time unsoldering a bunch of boards, and running the risk that I have destroyed the semi upon removal. You do bring up a good point though. I have been known to snag the ocassional TV set from the trash if for nothing else, the enamaled wire and all the little knobs.

Its likely, after experimentation and proof of concept, that we would have
an international frequency set aside for exactly this purpose. I'm getting
in touch with the right people to try to make this happen.

>Here in Aus, you could use channel 67 (the secondary distress channel, thus

Yeah, that might be another possibility for a frequency! I'm really curious
to see what Industry Canada suggests, they haven't gotten back to me yet and
must still be debating it.

More expense and more size, in using an oscillator type circuit. I really
think SAW chips are the way to go.

Might modulate it with something like a 555, and then control it with a PIC
chip. Definately would add a gain stage after the SAW chip.

Storage method could partially negate some of these issues; you can keep it in a shock-resistant case, out of the sun, for example. If the devices are maintained by a club, then the storage methods could be properly supervised. At any rate, I agree that, for the average maritime consumer, the $250 minimum, 'nearly indestructible' EPIRB is a necessity.

Of course, the regular EPIRB frequencies of 121.5 and 406 MHz are ideal in serious emergencies, but you don't want to deal with the problems if you've loaned one out and the user intentionally triggers it for something that doesn't really qualify.

Maybe it could be set up to transmit a beacon on another frequency for a non-life-threatenng activation, while the serious emergecy activation button would have a cover to prevent accidental triggering.

If you can do that with a 500mW-2W device that costs less than $100, I want to know how.

>Interfering with a
>tower to airplane communication which results in an airplane crash
>might be the worst case scenario. (Ok, I'm obviously stretching it
>here, but I'm trying to make a point.).

Actually, I think launching the world's entire thermonuclear arsenal at randomly chosen ground targets would be the worst case, but since we hams haven't accidentally done that yet, I suspect we can keep these theoretical boxes from doing it.

>One of the choices for frequency usage may be dictated by the watery

>antenna for efficient radiation, and, plus, may also cause
>difficulties in attempting to radio-locate the source of the signal
>(Think of the receiving equipment and how it will be doing the radio
>location.).

I was thinking airband (121.5) for the primary emergency signal, and maybe a MURS frequency or, (with their agreement, of course) a CAP VHF frequency for the non-life-threatening assistance signal.

This would be right in the range that most hams are used to fox hunting for, and would allow for a simple rubber ducky to be used, rather than a telescoping antenna that would break easily, or a whip that would potentially degrade quickly in salt air. While the ducky isn't ideal, it's nearly indestructible, and not too hard to allow space for.

Note that by non-life-threatening situations that the beacon could be used for, I'm referring to situations that do require assistance, but aren't particularly time-sensitive or dangerous. Capsized and unable to right, or adrift without serious weather approaching come to mind as examples.

>A weaker, but possibly more prevalent, form of the moral argument is

>risk.

Again, assuming this is being handled by a club, it could be provided only as part of a kit, thus allowing them to ensure that all safety equipment is carried.

>Now, consider that, during a typical
>day, five percent of the devices false positive. That results in 50

A light and sound combination on the device itself would allow the user to know if it was been activated. (The lack of these on ELT's being proof that the FAA doesn't think things through as well as it

shoudl, IMO) As far as alerting the rescue crews, unless everyone's carrying VHF radios already, you would have to have some sort of 'all clear' signal built into the radio that would be equally had to send accidentally in a real emergency.

>Also, consider the case where a false positive may be interfering
>with a legitimate signal. Radio direction finding one clear signal

>programmed part of some type, and this is going to increase the
>device cost.

Given the easy availability of PICs and other methods of programming the beacon, having them ID via morse wouldn't be an unreasonable demand. Just make it so it sends a tone, either modulates the tone or the carrier itself, and all-clears with, say, its ID immediately followed by OK. You don't want to call off the response to a real emergency if someone else accidentally triggers the hits their all clear.

Not necessarily. It could be done as a manufacturer-recyclable, so that returning the unit to be refurbished and tested would reduce the cost dramatically.

If the signal is coded so that it has two states, immediate life-critical emergency, being one state, and not-overly serious emergency yet, as being the other emergency, then this might work. If they were separated to be on two different frequencies, I don't think this is ideal. It would add to the size, add to the expense, and also add to the needed rescue equipment, as well as an antenna would be more optimial in one situation or the other. Since the small clubs & such would have no 121.5 finding equipment or recivers, they would have to buy that in addition, and possibly have to get familiarized and trained at using two different devices for DF'ing, in different situations, and different equipment, with different antenna lengths, etc. The worst possiblility, is being trained well and experienced in using the DF tools in the non-serious emergencies, but when it comes to the real serious ones that might happen once in a few years, they might have difficulty. Since most of the situations would be reasonably serious, at least serious enough that they are going to waste $20+ on a particular incident, I think just one activation with one type of distress would be ideal and quite sufficient. Two types of signals would add to the confusion of how to use the device, etc., and makes it twice as hard to design a device that can't be triggered accidentally.

>Note that by non-life-threatening situations that the beacon could be
>used for, I'm referring to situations that do require assistance, but

Right, this is likely the most common scenario this device would be used for. Time sensitve would be relative. In the summer, an hour would be OK, but 4 hours could become dangerous. In the winter, 35 minutes might be OK, but an hour and a half could become quite dangerous. Without wetsuits in the summer, an hour and a half could start getting dangerous. Without wetsuits in the winter, consider yourself dead in any case. :) Vancouver is a protected bay with reasonably warm waters during the summer & winter, but places like the SF Bay area I imagine would be even more time critical.

>A light and sound combination on the device itself would allow the

Either that, or have the device activated in such a way, that the action
would be extremely deliberate and obvious.

All modern garage door openers are digitally encoded.
The chances of randomly opening garage doors accidently
with an unmodulated carrier are very unlikely. Imagine the
product liability claims if doors could be tripped to close on
kids or cars without warning--due to a stray signal?

This is new to me -- I learned something here, Bob :-)

The problem makes me think of blowout coils. They're used in contactors/switches for high-current DC applications. When you open one of these contactors, the current tends to arc from one switch contact to the other. The current from the arc flows through the blowout coil, and the magnetic field that the current creates blows the arc out of the gap.

Couldn't that work here?

... Rich

Similar devices exist

http://www.divernet.com/blandfrd/pblhome.htm

They are made in the UK, cost about USD $210, and are too bulky. They transmit on 121.5 & 243 MHz EPIRB frequencies, and I've been told that those frequencies should NOT be used for the level of seriousness that we are intending for these devices. A small boat is overturned with a broken mast, they need a tow to shore before the boaters become hypothermic.. Not super time critical, but it could get very serious if the length of time was long enough.

Ian

Hi,

If you are interested in the use of DSP for radio receiver, perhaps you
could take a look at my new web page,
that describe a program I wrote for a 56002EVM board :

http://perso.libertysurf.fr/thierry.leconte/demod.html

Don't forget A.C. vs. D.C. ratings. A.C. voltage ratings are
typically much higher because it is significantly more difficult to
interrupt a D.C. arc.

If anybody has a good, inexpensive source for 70vdc (minimum, 125vdc
preferred) fuses, please let me know.

Use "Viteruos enamel" glass type, .67 ohm, 1 watts resistor, which will
expolde if a "parasitic oscillation" happens, which is what most of these
fuse resistors are for.

Joe,
I will be happy to keep the group informed. I will be presenting a paper at the Central States VHF Conference on July 28 in Dallas. I also have gotten the go ahead to write a four part series for QEX from Doug Smith. I hope to use the material I am presenting for Central States and expand on it for the series.

My current design uses the Tayloe detector on a small Radio Shack protoboard. It has a 74CBT3253, 74AC74, 74AC04, and two LT1115s. I drive the clock with a HP8640B signal generator. The outputs of the two LT1115 op-amps directly drive the sound card as I and Q. The PC does everything else. You won't believe the performance you get. And its all in Visual Basic which most mere mortals should be able to program in.

By the way right now I don't even have a front end low pass filter. On 40 M it works pretty good without it even though I don't recommend that. I have a lot more work to do but it is already working extremely well.

I think a lot (but not all) of the negative responses you've gotten might have been due to the wording of your original question:

>First of all, do any such inexpensive radio transmitters exist? (I was >hoping in the US $20-30 dollar or less range) Possible? The transmitter

I and others pointed out how unlikely we think it would be for you to find a commercial transmitter meeting your criteria, and why. But this is a very different thing than a unit that can be designed and built for free by volunteers, and which doesn't have to meet any legal requirements for stability, spurious emissions, power level, and so forth, which won't undergo extensive testing or reliability assessment, which won't incur any liability in case of failure at a critical moment, and which can be sold at essentially the parts cost. What you're now proposing -- a unit containing maybe $20 or $30 worth of parts, designed and built for free, and unburdened by any legal niceties -- is probably possible. Now that the newsgroup readers have a better understanding of what the rules are, I'm sure you'll get more good suggestions about how to proceed. I hope you'll let us all know what you ended up with when you've gotten them all built and in operation.

Hello,
I'm planning to build a simple receive antenna for portable scanner use made of a copper wire (60-70cm) connected directlly to the BNC.
I'll use it to improve the reception in the 100 - 900 MHz (mainly 100-200MHz).
I'm wondering how will this antenna perform and which bandwith will it have.
Another question: how can I improve the bandwidth of the antenna (i have been told that is possible to put some capacitor somewhere to lower the Q and rise the bandwidth) for using it over all the bands (100-900MHz)

Does anybody help me?

Thanks,
Roberto

CW19 (http://www.geocities.com/cw19kit) is a morse code practice kit.
Features:
- Decode manually keyed morse code from 5WPM to 20+WPM.
- Use with Hitachi compatible LCD modules (2 row x 16 chars)
- Display wrong keying sequence
- Support all A-Z, 0-9, and standard symbols
- On screen configuation menu, use your morse key to configure it
- User select WPM speed by on screen menu
- User select buzzer pitch by on screen menu
- NO JUMPER to set.
- You may keyin your callsign as welcome message
- Contain 26 sets of Alphabet for copy practice
- Contain 10 sets of Number for copy practice

I'd just stick up a 1/4 ground plane for the lowest freq to be used.
It should work well enough for gov work. Being as you want 100-200
mhz, just cut it for about 100-150 mhz. It will work well enough on
that range of freq. It will still receive the high UHF stuff with a
less optimum performance. If it's not good enough, make another one
for UHF. They are very small and cheap to make. Don't add anything to
broaden the bandwidth. You don't need it for receive purposes, and it
will just reduce the performance on the range you cut it for. You
could also try a discone or similar, but they cost more. A GP can be
made from a so-239 and 5 pieces of wire. Cheap. MK

HV fuses are history, but not used with modern transmitters - only amateurs who don't know better. much better practice is to use a smaller (47 ohm) series resistor but higher power in the supply output and have the fuse on mains side

As far as I know I was always talking about part & assembly costs, so I'm not sure where anyone got the idea that my $20 - $30 range had to be the end-resulting product cost that this might sell for on the market, or what a person might have to pay to obtain one of these devices. I was simply discussing the cost of the parts and the cost of assembly, which I still think is quite doable for $20 - $30. Costs for testing, legalities, marketing, overhead, design, or whatever costs there may be added over and above that, sure, one could envision so much of this so that the price could end up being ten thousand dollars a unit, especially if the volume was low, but I don't think I ever insinuated that all this should be included in the $20-30 range (and if I did, I certainly didn't mean to).

In fact, one of my opening statements was this:

>As a side note, I'd like to remind people that a whistle costs about 5
>dollars, and a cheap water-submerisble transmitter I think could be built
>for 20.

I didn't say sold for 20, but perhaps some people interpreted it as such?

Source record: 51808

I rescued an Murch 2000A from the dumpster. It's not in bad shape cosmetically or mechanically. However, the middle inductor's insulator is melted at the end, so the unit is out of round. I guess the guy ran too much power through it.

Anyway, does anybody have the middle inductor for one of these that they will part with, or possibly the whole unit for parts? I'd really like to save this one.

Alternatively, has anybody experimented with replacing just the insulator? The coil itself looks great.

Thanks much,

Norm/KQ6SD

Brian,

I think you would be better advised to buy a decent used 2 meter radio. They use pretty sophisticated circuitry if you want a modern one and they are not really cheap. If you look around, OR you don't mind crystal control, I would think you could find a used Icom 22S for around $50.00!

Hello,
Thanks for reading this post!
I have a late 50s rack transmitter. The power tube is missing so I don't know what it was. The transmitter was setup for 5 band, AM/SSB operation. The panels are silver gray hammertone and they are in good condition.
The PS and Modulator has some rust on the transformers but the chassics looks OK.
I don't know if any of this stuff works or not but I figure the parts are worth about $100.00. Shipping on you or delivery within 150 miles of Springfield, MO.
It has 2 great looking dials and it would make someone a great old homebrew system once its restored .Pic's are available.
E-mail me with questions.
Tnx and 73...John

Why in the name of all that's holy do these people think we'll
informatively answer questions like this as a group? As radio amateurs,
we _RESPECT_ communications law, and understand that by scoffing it we
risk not only legal sanctions, but ramifications to the allocations of
our spectrum as well.

To the B/C radio pirates, freebanders, CB'ers running amps over the
legal limit, and others who pursue illegal radio: _PLEASE_ don't bring
your questions for help here! If it is a legitimate pursuit, we will
(normally) be happy to help you. If you're looking to disrupt existing
services (as pirate radio will), please don't ask here.

Patents are public documents. Purpose of patent is that author or owner
gains money out of possible commercial production.
If you can not see it and try it how you can eventually produce it.

Selling kits would be illegal but just making I think not...

I would rather call it translator than mixer. It translates baseband
from HF to 0 Hz.

From what I can see this is just fine example of raping Shannon-Nyquist
theorem. This is what happens whan you get aliasing situation (bad
aliasing filter for example). Result sampled signal is garbage.

Same thing happeed to me in mentioned software when I put insufficient
number of points (iterations per second) in parameters - result was not
good at all and envelope of signal was floating in harmonic way with
frequency being equal to difference. But even then I did not realized
what Dan realized although from today point of wiew it is so obvious to
me.

There are number of ways to do that. Up to now doing so was considered
bad. Now it turned to be useful :) .

Same with this - you cannot hear that.

> In my view, any switching mixer *must* create both sum and difference
> frequencies. (Indeed, a switching mixer *also* will create sum and

It removes one of them with phase network after.
Speaking about phase networks - I need to shift Q by 90 degrees in range
300 Hz to 3000 Hz and get orthogonal axes on XY plot. All particular
frequencies are sine waves. When you do shift sine wave by 90 degrees
you get cosine wave. cos(x) is first derivation of sin(x). Classic
derivator won't work here - that is why we use networks.
Somebody mentioned that he used PC to do that. OK, sample I on left and
Q on right and then you derivate right and sum that two ones properly.
Is it so simple or I am wrong in something?

If it is, I can do so with PIC 16F874.

> Perhaps we can encourage a deeper discussion.

I will be glad to participate.

Jerko,
First of all make sure that you understand how a phasing receiver works in analog. Next you should read The Scientist and Engineer's Guide to Digital Signal Processing which can be found for free at www.DSPguide.com. Next you should read an article by Richard Lyons called Quadrature Signals: Complex, But Not Complicated, which can be found at http://www.dspguru.com/info/tutor/quadsig.htm on the www.dspguru.com site. This should get you started. If you want to go further you should read Understanding Digital Signal Processing also by Richard Lyons, which you can buy from Amazon. All three of these references are excellent but I would recommend reading in the order that I have given them. Don't let the math scare you because using DSP in practice is actually easier than the math implies. I don't really understand it all but I can use it in practice.

73,
Gerald

Subject: DSP od I and Q

Hello!

I am reading homebrew newsgroup regarding Tayloe mixer and I am interested in doing I and Q with DSP. Could you please point me on appropriate resources regarding this topic.

For first it would help me to know how exactly you need to deal with I and Q using DSP.

I never used any DSP techniques, but I am willing to learn them.

Jerko,
First of all make sure that you understand how a phasing receiver works in analog. Next you should read The Scientist and Engineer's Guide to Digital Signal Processing which can be found for free at www.DSPguide.com. Next you should read an article by Richard Lyons called Quadrature Signals: Complex, But Not Complicated, which can be found at http://www.dspguru.com/info/tutor/quadsig.htm on the www.dspguru.com site. This should get you started. If you want to go further you should read Understanding Digital Signal Processing also by Richard Lyons, which you can buy from Amazon. All three of these references are excellent but I would recommend reading in the order that I have given them. Don't let the math scare you because using DSP in practice is actually easier than the math implies. I don't really understand it all but I can use it in practice.

73,
Gerald

Subject: DSP od I and Q

Hello!

I am reading homebrew newsgroup regarding Tayloe mixer and I am interested in doing I and Q with DSP. Could you please point me on appropriate resources regarding this topic.

For first it would help me to know how exactly you need to deal with I and Q using DSP.

I never used any DSP techniques, but I am willing to learn them.

> Is it so simple or I am wrong in something?

You are right, you sample I on the left and Q on the right. I then do a
Complex Fast Fourier Transform on the input and do the filtering and
sideband selection in the frequency domain. Since the Tayloe Detector gives
I & Q directly all you need to do is to use low noise amplifiers to drive
the sound card. Very simple.

>
> If it is, I can do so with PIC 16F874.

Unlikely. You need more horsepower than a PIC would have. Todays PCs with
sound cards are much easier to deal with and are extremely fast.

Hey gang,
I'm building up a charger for my 12V lead acid batteries. Is it true
that it is safe to leave this type of battery on a trickle charge of
13.80 VDC from the charger?

If so, what is the expected current at this voltage?

Tnx es 72

Not a good idea to set the voltage. Better to adjust for a trickle of current.

The filtering in the frequency domain is one approximation to a
Hilbert transform, which is really what is required here.

Manufacturers usually recommend constant voltage trickle charging for lead-acid batteries. The trickle charging current will of course depend on such things as battery size, temperature, battery condition, etc., but should decay to a fairly low value when the battery is fully charged. I've used a chip from Unitrode (now Texas Instruments) UC3906. This one is temperature compensated and will take care of all cycles of battery charging and maintenance. It requires just a few external components to work.

Johan

The UC3906 is specifically for gel-cells IIRC. The charging regime is
not optimised for wet cells.

Don't know what Bob has, but I suspect he would have said gel if that
was the case ....

Forget it.

The normal simple Lamba/4 antennas hava a useable bandwidth
of about 40 % of the center frequency .

I recommend the use of a telescope antenna, where you can
adjust the length manually.

The rubber coated spring coil antennas have a useable bandwidth
of about 10 %.

Broadband antennas are complicated and not good for portables.
You will need a few different antennas for covering the whole range.

pr.

Greetings,
Any ideas for restoring car batteries for non-critical applications? A
found only one reference, where the author used sodium-sulphate
(Glaubers Salt), but the drugstore asked $18.00 for 100 grams of the
stuff, so for that price one might as well buy a new battery :-)
Thanks
George VE7CEH

I am the original poster on the HV fuse thing. I already have a 50 ohmm
50 watt in series
with the + HV lead being fed by the HV fuse. I also have Magnetic ckt
breakers on the xfmr mains.
Even with that I think with a flash over I would blow the full wave
diode's IF it were not for the HV fuse in there also. Have had several
flashover's of GS23b 4cx1600U on 432 mhz. Afraid to remove the HV fuse
since it works so well to protect the diode's in full wave bridge ckt.
Do you think the 50 ohm reistor will protect the diode bridge without
HV fuse. I am afraid to find out so far.

Hi Paul,

Who says such resistors are purely resistive up to at least up to 30
MHz?

By how much do they deviate from the ideal?

Don't believe anything the magazines and manufacurers say without some
kind of authentification.

The fact that something might by chance happen to work is no
indication whatsoever how well it works.

All maufacurers of dummy loads for amateur use should be prosecuted
for infringements of the trade's descriptions act.

And all radio magazines whch advertise such perfect wares should be
likewise prosecuted.

But don't worry about it too much or you will go potty..

3957. Parts for sale

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-29 00:11:13 UTC
From: Scrounger <bmurrey@amexol.net>
Message-ID: <9JP_6.22$q34.26119@news1.iquest.net>
Source record: 51754
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew

I'm selling off some excess parts here at the shack. XYL says they have to
go or I can't buy the new K1 I so desperately need.

PN2222A's

50 for $4.50 inc shipping
100 for $8.25 inc shipping
200 for $15.50 inc shipping

BNC Panel/Chassis Mount connectors (I have 1000)

25 for $10.00 plus 2.40 shipping
50 for $17.00 plus 4.00 shipping
100 for $30.00 plus 6.20 shipping
200 for $56.00 pluss 8.00 shipping

I also have 2 5K 10 turn precison Knob Pots by Bourns.
These list for about $35 each in most catalogs, or more even.

They are pulls from another project I was working on but I have checked them
and will guarantee they are in perfect working order. I'd like $15 each,
free shipping.

Interested?

Email to bmurrey@amexol.net with any questions you might have.

Depends on what you mean by "trickle charge".

I consider 13.8 to be a little high for most batteries. It's better to set the current, if you can monitor that (and you should). I've been using group 24 batteries (a common automotive/marine size) and gel cells for years. The 24s do well on a float/trickle charge of 200 to 300 mA, which I get at 13.2 to 13.6 V.

There's lots of stuff to read on the web. The many sources of advice that you'll find won't all agree. The above is my experience.

The sources I liked best are the car battery FAQ at http://nyquist.ee.ualberta.ca/~schmaus/batfaq.html and the deep-cycle faq at http://nyquist.ee.ualberta.ca/~schmaus/dcbat.html

It can be done. But the fact that lead-acid battery recycling is such a big business makes me think it's not really practical.

What do the recyclers do? They chop up the batteries and recover the lead for making new batteries. If it made more sense to "restore" the batteries, I expect they'd be doing that, but they aren't.

Well if you read Vishay or Dale data sheets they use a very good term "Virtually" Non Inductive. But that still means that they not purely resistive and truly non inductive. Actually i run 4000 watts, i wonder if the FCC believes its virtually 1500 watts.

But these surface mounted packages work very well for passive grid terode amps.

I've got some made by a company called Carborundum. I haven't tested them yet, but they do claim zero reactance. They are tubular, and they seem to be made of some kind of composition material, with metallized ends.

These are the best resistors to use. The so called Globar type. They very hard to find and very expensive, Surplus Sales sells them at stupid prices. I have never seen a true 50 ohm version, most are 47 ohms. You probably going to have to get 2 X 100 Ohms to get a good 50 ohm resistors. Anyway at the prices they sell these resistors for i would just go out and invest in Bird load, it will last you a life time and you will never blow it. The MFJ cantenna is the biggest piece of crap i have ever come across. Likw most of their products.

My motorhome uses two 12-volt deep discharge RV batteries in parallel. They are under constant charge by the "smart" inverter at an indicated voltage of 13.2 volts. The trickle-charge current is around 200 mils or so. Batteries seem to last indefinitely at this charge level with occasional attention to water level.

Those resistors are/were used in the famous Heathkit Cantenna. I have always measured a d-c resistance of 47 ohms and the impedance as measured by the AEA/Tempo CIA/HF also shows a real part of 47 ohms and negligible reactance up to 30 MHz.

I think the Cantenna was something like $12.95 back in 1970! Still works fine . . .

Back in the 70s, recycling batteries was pretty common. I recall one battery shop that had a massive charging system and hundreds of batteries sitting on charge at any given time. Basically, all they did was flush them out and pour fresh electrolyte into them. Occasionally they would 'behead' a battery to get to the plates for a more thorough cleaning, then seal it back up. As I understand, the typical cause for the battery's demise was deterioration of the plates. Overheating may have caused them to warp and short, or a layer of scale had built up on the plates.
The costs to comply with environmental concerns (and fire dept. regulations!) nowadays would certainly prohibit doing the type of work this shop did.

I have a Red Hot Norcal 20 and am quite happy with it. I haven't noticed any chirp problems. The receiver is quite good in terms of both selectivity and sensitivity, better than my TS-570D(G). It comes with a Tick 1, but the instructions do suggest upgrading (I did). Still, you get a lot of radio for $150.

There are a lot of parts, but the manual is well-written and assembly isn't difficult. All parts mount on the p.c. board, so there are no wires. The checkout is done in sections as you assemble it, so it's hard to go wrong. It was fun to build and is fun to use.

I put some recent pictures of the 17 meter DSB rig on my web site.
Just go to the URL that appears below and click on the "17 meter DSB"
link.

I decided to use one pole of the 4 pole double throw TR relay to
switch the VXO output from the transmitter balanced modulator to the
receiver's mixer.

Looks like the RX will be direct conversion with one stage of RF amp,
diode ring mixer, simple SSB low pass filter, and enough audio
amplification to drive a speaker. (I'll probably resort to an LM386.)

Ken

I have the original Norcal 20 and it's dynamite. There was initially considerable chirp but there was a mod to fix that and I believe the Red Hot version already includes the mod. If not it's pretty simple.

The main thing about the RHR/NC-20 is the receiver. Dave made a choice that receiver performance was more important than power consumption. For TOIP, the receiver far outperforms any other receiver in it's class, and many higher end rigs. When the band is crowded, this is a very real and obvious difference. Strong nearby signals that will give my K1 or Icom 706 fits, the NC-20 will blithely ignore. However, there is a price. The rig consumes about twice the receive power of other QRP rigs, so if your interest is backpacking, it may not be the best choice.

As far as the TiCK, just socket the thing then whenever you get a round tuit, pop in a TiCK 4.

The rig isn't trivial to build, but Dave's instructions are excellent, so if you are at all reasonable with the slobbering iron it should be no trouble.

Operating the radio is somewhat different. Since it uses the AFA for frequency annunciation, and there is no dial, you never actually have to look at the radio. This makes it feel quite a bit different. I've often thought that would be ideal for mobile, but I've never tried it.

The big delta is that as far as I know, Dave hasn't been shipping them, so if you order direct, you may be in for a long wait. Every so often one shows up on QRP-L so that may be a better route. The problem with that is you need to be fast. I don't think I've seen a RHR20 last more than a couple of hours, so if you work for a living, and can't keep a close eye on your email, it could be tough.

3972. Re: Please send me information how to get started into serious Remote Ham Radio Operation.

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-29 14:33:13 UTC
From: Bruce Muscolino <w6toy@erols.com>
Message-ID: <3B3C91A9.C892482@erols.com>
Source record: 51769

Marcus,

In general, anything you would do at a "remote" location you would also do at a fixed location. There are only a few parts to setting up a station, they don't vary much whether you're going to be there for a day or forever!

The radio is the same. Of course radios for portable operation can be simpler or often tend to be less valuable than those used at a fixed location. Examples are QRP radios made especially for portable use.

The antenna is the issue. Can you leave an antenna installed at your portable location. If so your installation is much simpler. Depending on the type of antenna you will only require a tuner. IF you can't leave the antenna installed, or if you are contemplating "pseudo mobile" operation it gets more difficult.

By "pseudo mobile" operation I mean traveling around, going form motel room to motel room and having your radio there for companionship! Here you are faced with an ever changing antenna installation problem. I like the concept of a mobile whip, either designed to be installed quickly in a motel room window or used while mounted on the car. If you ask for a ground floor room where you can park close to the room, you just run a short length of coax out the window to the antenna and go on as you would on the road!

In short we need more information on what you are planning. And remember, you require a license to operate ham radio equipment!

John,

As you have heard, there are specific frequencies set aside on 6 meters for Radio Control. Ham radio is generally a hobby where people talk to each other, Talking to an airplane or car is not quite the same!

I don't know what kind of experimentation you have in mind, but I wonder if the Niko car is the best platform for what you want to do. It would seem to me, and this is from a few years of experience with RC cars and airplanes (20 some years ago, but valid nonetheless) that you would be better off with a more open design. I know you already have the Niko, but consider what you are planning. You will want access ot all parts of the system for experiments, and most commercial RC cars sold with radios use a brick type of integrated radio that is hard to modify!

Of course you will have to convert the radio to 6 meters. Not an especially difficult problem if you have any electronics background. Remember you will have to convert both the transmitter and the receiver to the same frequency. You will also want to be careful to check out the frequency because you can cause interference to others using it. Radio Control depends on only one carrier on frequency at a time. The cost of having an airplane shot down because of interference is quite high!

Ken,

Just a thought. The best place to find information about QRP radios is QRP-L. YOu can join the list (QRP-L@lehigh.edu) and find lots of RHR users. I had one that was part of the original NorCal group buy. I recently sold it (unbuilt) to a friend down in Texas who built it and is very happy with it.

It sure complicated things for me. I always thought quadrature signals
were 90 degrees different in phase.

3976. Help me locate aluminum tubing

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-06-29 15:23:36 UTC
From: jimmy john <jj@sandwitch.org>
Message-ID: <4A8A59F2BDCDD311BFC800508BA36AC80965CAD0@www.premiersi.com>
Source record: 51773

I've been wanting to construct a yagi for 6M, but am finding tubing hard to get at reasonable cost. A local supplier quoted me $6.75 (PER FOOT!) for 60 feet of 6061 1/2" x .068 ID. (I'll go ahead and plug this "ripper-offer": amro.com - stay away from them)

Buying lengths longer that 8' seems difficult because then you get into more costly freight handlers instead of UPS or other regular delivery services. While Texas Towers seems to have about the best prices I've seen (abt. 80 cents per foot), anyone know of others that have even better prices? I need about 9' for each element and 24' for the boom. I'd really like to NOT splice things so it's as strong as possible.

Looking in central Indiana area, preferably.

thanks,

jj

You probalby cannot, the RF strip and PA may not handle 52 Mhz. Your bet
bet is to get a 6M transciver, or a transverter.

Source record: 51778

What are the inductors used for that you are talking about ? The reason is in the way they are used. Some make for beter impedance matching. If I remember correctly when they are center tapped you get 1/4 the reactance but if they are tightly coupled then this is modified quiet a bit. Just going by an artical I read a while back on the 88 milihenry telephone loading coils, the coupling makes what you would think of as 22 mh a low value and the actual value of each coil is more.

Yes... buy a new one, George. Essentially, a dead car battery is a dead
car battery. If you lash out $60 (is that what a battery with a 3-year
guarantee costs in VE?), and treat it gently (no nasty starting of cars,
and a bit of full discharging and recharging from time-to-time), I
understand that it will probably last you a lifetime. However, I've
never done it myself - and I doubt if anyone has!!
Ian.

You might check local metal salvage yards.

In Phoenix, we have a place called "Davis Metals" downtown on Washington Street. They are a metal surplus place that sells aluminum sheets for $1.50 per pound (they have scads of it!) and tubing for $3.00 per lb. You can get a fair amount of aluminum in a pound! They have a wide range of tubing sizes, but not enough different ones to get telescoping elements.

You have to know the current at 120 VAC. You are assuming
the power supply is 100 percent efficient in converting from
120VAC to 12VDC. You math is fine as far as it goes, but it
is based on the assumption of 100% efficient voltage conversion.

Hi there,

If your radio shack is on a 15 amp circuit (supplied by a 14 gage wire) and you are drawing 14 amps for some lightas, a computer, a monitor, a battery charger or two for the HT(s), maybe a coffee pot, and then you transmit....

What lights are dimming? The whole house? How old is the wiring in the building. Just on the one branch circuit? Maybe you are running the lights and the rig from a discout store extension cord? Is your central air on? It sounds like 2.3 amps is the straw that broke the camel's back. Keep the rig... get a new house <grin>.

Since he knows the transmitter's DC current draw and voltage,
transmitter efficiency doesn't enter into the calculation. The power
supply efficiency does. Still not enough current draw that should
affect the AC voltage and make the lights dim. It could be that there
are some poor (corroded, high resistance) connections along the way.
If the radio is on the end of a string of outlets, check each one on
the same circuit for good, tight, clean connections. Check for
aluminum wiring if its an older house. This stuff was famous for
corrosion and loose connections.

This could be a general question rather than a question specific
to the MLA2500. I am in the process of putting a 4CX800 in
the amp. Don't tell me not to do it because I am 75% finished.
All I have left is the grid bias supply and am trying to figure out
just what I am going to use as a chimney. I'll probably wrap
some sort of silicon rubber sheet around the tube like the Alphas
did in some of their amplifiers. My question is do any of you
have any neat ideas on how to design the grid bias supply? I need
about -55 volts or so. The mods I have seen use a fixed grid
bias, but I would like to put something like -100v on the tube inbetween
actual transmissions. This would be something like the "electronic
bias" used on some 4-400 and 3-500 amplifiers. In that method they
use rectified RF to turn on and off the cathode bias.

So I would like to have -100v (or up to -150v) on the grid while the
amp is keyed but no RF input. As soon as I get RF input the grid
bias drops to -55v. I guess I could use a string of zeners and somehow
select the full string when idle and then one diode when RF is present.

Have a chat with Niagra Falls power station senior mainenance
engineer.

Do the generators slow down when you speak into the microphone or hold
down the key?

No need to bring up the subject of advanced mathematics. If you have
sufficient understanding of 8-year old kids' arithmetic there's
nothing to worry about.

Except perhaps your electricity bill. ;o)

NOT true in my case! I've used auto batteries as my basic shack supply
for over 20 years, and they last just about the same time in the shack
as they do in cars. I've used several kinds of chargers, some homebrew,
some commercial; once even windpower. About the only thing someone has
suggested but which I have NOT tried is mounting them on a "shaker" so
the acid is stirred mechanically!

>the lights dim!

Rf in the shack can cause this especially if you use flourescent lighting. I had an all band dipole and one leg ran close to the shack. On 17 meters, I would completely extinguish one shop light on voice peaks. No problem on other bands. Rearranging the antenna, baluns, and ferrite will cure this. If you are dimming incadescant lights, I would look into the wiring, connections ect. as others have suggested

Source record: 51705

The best way to treat a non-deep cycle battery is to keep it as fully charged as possible, never discharge it completely, and to never shake it. Discharging the battery too much damages the plates and the lead oxide, lead sulfate coating, as does shaking it, which flakes off the oxide and sulfate.
Non-deepcyles are designed for temporary high current flow, with minimal discharge, followed by immediate re-charge, hence, the car battery application, starting the car followed by a recharge.

At this point.. I suspect it is RF getting into it..

Because even if the astron power supply was only 50% effeicient, we
estimated that it was drawing 2.3A if 100% efficient, So -- 5A on a
120V circuit running a light bulb and the power supply shouldn't make
it dim that bad..

For what it's worth, I'd love to redo the wiring in the house.. The
telephones were wired with straight wire.... (not twisted pair) Cross
talk, RF, all sorts of crap gets into it..

Did you actually measure that current or did you get it from the transmitter specification ? It should also noted that some meters may give incorrect readings, when exposed to strong RF fields.

>If I recall correctly, P=VI, so 276 watts...

That is the DC power into the transmitter.

>At 120V AC, thats 2.3A...

You have to remember that traditional linear power supplies are not 100 % efficient, but instead generate quite a lot of heat. The power to generate this heat is also taken from the mains and the efficiency may be as low as 50 %, thus the double power has to be taken from the mains. That would be nearly 5A rms or 7A peak, assuming the current is sinusoidal.

However, a traditional linear power supply only draws current from the mains as long as the storage capacitor voltage is lower than the instant transformer secondary voltage. With a sufficiently large transformer and capacitor, the output voltage is close to the secondary peak voltage and the rectifiers might conduct for, say 36 degrees of the 180 degree half cycle. However, since the total charge needed remains the same regardless the size of the conduction angle, all that charge must be transferred at that short time. Thus, the peak current in this example would be 5 times the rms current or 25 A. (in modern power supplies "power factor correction" is required to extend the conduction angle and thus reduce the size of the current peak).

The voltage drop in house wiring during this peak current flattens (distorts) the _voltage_ waveform delivered to other loads such as the light bulbs, thus the average power delivered to the bulb drops.

>Now, that doesn't seem to be nearly enough as using the thing makes
>the lights dim!

Did it actually dim or just flicker when the transmitter was turned on or off ?

The eye is very sensitive to light changes, but adapts quickly to the new level. The light output from the bulb depends very strongly of the filament temperature, which depends on the average power and hence the square of the voltage. In practice, the light output from a typical bulb is proportional nearly to the cube of the voltage, thus, a 1 .. 3

percent voltage change is easily visually observed.

If the light appear to be dim for the whole transmission time, then it is reason to suspect that the house wiring is inadequate or the connections are not tight enough or they are corroded. Such bad connections will dissipate a lot of power when heavily loaded, so there is a considerable fire risk, thus, such connections should be checked.

If a bad connection has a 1 ohm resistance, with 5 A rms load it will dissipate 25 W, but if the power supply draws 25 A during 20 % of a cycle, the peak dissipation will be 625 W and the average dissipation 125 W with a very real fire risk, thus the current waveform has a great influence on the dissipation in bad connections.

"Ordinary" automotive batteries are indeed designed for this kind of
service. But I've heard from folks who have obtained battery lifetimes
many times the usual automotive lifetime by keeping them on a float
charge and otherwise treating them well, as you recommend above. And
that advice applies to gel cells, too.

Or put another way, it prevents the power supply line from responding to the audio frequency range and coupling the signal between stages via the common supply line. If there's enough coupling via the supply line you will get feedback, typically called "motor boating" because it sounds like that - "put, put, put". If you hear this in an old radio, it's a pretty sure bet that one or more decoupling capacitors are defective.

Not heard of 'decoupling resistors' before !

Decoupling capacitors are for getting rid of noise on supply lines/DC voltages -
ie, trying to maintain a clean DC supply to a part of the circuit, provides a
low-impedance to ac on DC supply lines.

Must of the time "de-coupling" components in AF circuits are used to "Block" DC current from entering a given stage of the circuit.
Many times the parts is a capacitor, which "blocks" DC current.
If a resistor is used, it will not "block" DC current, but will limit the amount of current that will flow in the circuit.
A DC voltage may be used to operate a given portion of the circuit, but must be removed in an other, the capacitor will "block" it, but allow the AF to pass into the next stage.
A capacitor will "block" DC but allow AC to pass, dependent on the capacitence of th cap and the frequency of the AC impressed on the cap.

decoupling resistors are often used. They go in series with the supply line to provide a higher impedance, making it easier for the capacitors to stabilize the line (i.e. an RC filter).

What a crazy thread! Basically, de-coupling is just as the word says.
Some component, capacitor or resistor, that will keep the AC (audio or
RF) component from finding an alternate route to where you don't want it
to go. That may imply sending it to ground, or attenuating it.
Its a conceptual thing and you can't simply label a component as
'decoupling' without looking at the whole circuit.

Thats really not a 'wrong' answer, but isn't the one that would win in multiple choice these days. Ain't many push-pull RF output stages that have been common in the past generation, but this was very often the case in times gone by. Look at any old 30's rig with a pair of 10's or 50's and you will see the answer is indeed correct. If you're from the Bash, or bashing-Bash era, you probably don't realize this.
My immediate answer to the original question would be totally different and include the term "Q".

Does anyone know where I can get 6 caps....100 Mfd @ 500 Volts...
prefer twist lock can type...size on the old ones is 3.25 Inches high and
1.5 inches in diameter......can't take anything much larger than in
height and nothing larger in diameter than that.....
thanks for any help anyone can offer......
John k9uwa

>aluminum wiring if its an older house. This stuff was famous for
>corrosion and loose connections.
>
>
>

Good advise. Then, having done all that, try narrowing the problem down
by a process of elimination:

1. Replace the transmitter with some car headlight bulbs drawing about
the same current. Does the problem go away?

2. Replace the power supply with another one. Does the problem go away?
If it does, then your power supply could have developed a leakage-to-
ground fault (e.g. through breakdown of transformer winding insulation),
which is potentially very dangerous.

3. Run the power supply and transmitter from a power outlet in a
different part of the house, or at a neighbour's house.

> Symantics...
>
Symantics is important - if you ask an engineer for a "decoupling"
circuit you'll not get a DC block. Decoupling blocks AC and passes DC.
Coupling capacitors block DC and pass AC. Two totally different things
which are applied in two different portions of an audio amplifier.

4032. Re: A Stupid Math Question

Newsgroup: rec.radio.amateur.homebrew

"Making the lights dim" is also very vague and subjective.
I'd to know the AC voltage with and without the load.
Sometimes only a few volts change will produce a noticable
effect on a bulb's brilliance..

What you are experiencing is quite normal. All your math, although correct, is based on average current draw from the wall. When you transmit, chances are, the transmitter, on peaks, depletes the charge on the energy storage capacitors in the power supply. Yes, they are for energy storage as they are typically FAR too large for "filtering". When the charge is depleted on peaks, its just like turning the power supply on, as the inrush current must restore the energy drained from the capacitors by the transmitter. I think if you measure the peak current our of the wall, it will be far in excess of the average current. That's why the lights dim.

I believe the San Bernadino Microwave Society has presented such a scheme in one of their publications. Rather than phase lock the critter, I think they INJECTION locked the magie with relatively good results. If I remember, the noise sidebands ended up about -70 to -80 dBc; not bad for a power microwave oscillator!.

4041. What are the useful bits from this 10KV lab power supply?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-03 20:04:10 UTC
From: Ken Hoover <ken.hoover@DIE.SPAM.DIE.yale.edu>
Message-ID: <MPG.15abef40dd214a81989682@news.yale.edu>
Source record: 51738

Greetings-

A non-ham friend rescued a 10KV power supply that someone in another building (probably a research lab) had sent to the trash. When he told me what he'd found and that he intended to gut it and use it to rack VCR's or something, I *had* to go take a look.

When I went down to see it, he had removed the font cover which exposed a 4-1000A tube assembly which, I assume, was used for fine control of the power flow. Thinking they would look cool on the shelf in my shack, I removed and took home the tube/chimney/base and set them as shelf decor in my "shack" where they do indeed look cool. 8-)

However, I realized the next day (hey, I'm kinda slow sometimes) that a 10KV power supply in a nice 5 foot rack represented all of the the most expensive components of a nice amplifier -- especially if I reunited it with its tube.

The manufacturer listed on the front panel (Kilovolt Corporation of Hackensack NJ) must be long gone because I can't find any references to it at all on the web. I can't find a date label on it but it has to be around 20 years old. The power supply is rated for 10KV and 250ma and is excellent condition overall (no dust, strange smells or scorch marks). I dare not plug it in, of course.

Any thoughts/suggestions would be appreciated as to what bits are worth grabbing out of this. I can basically have any of its innards that I want.

I've been doing some reading and figured that, at minimum, the transformer, possibly the rectifier circuit and some of the high-power resistors out of this thing might be useful. It has a couple of massive capacitors (10KV 6/6mfd and 12KV 3mfd -- I told you they were big!) which, judging from their age, probably have PCB's in them so I'm not going to mess with that.

My key question is whether the main transformer -- which takes 208V single-phase input and has an output tap labeled "5000V" -- would work to drive the 4-1000A at ham levels. Specifically, if I need (according to some stuff I found on the web) about 3700V at 0.7A to properly drive the tube could I get it out of a setup built around this transformer?

Please send email with suggestions/thoughts to my callsign @ arrl.net. I'd be especially interested in amp schematics that incorporate a 4-1000A tube.

I'm assuming that you have tried all the usual places. If you can't find them at places like antique electronics then you might try taking a page from the guys that restore old radios. A lot of .1 and .01 high voltage caps where the rolled paper types that are now impossable to find so what they do is hollow out the old ones and then insert modern equivalents and then seal up the old cap. You might try that with the cans if you still have them.

Now, wait a minute Dick. Are you telling us that W1AW has been
transmitting A2 all along? I don't think so. If so, I've worn out a
switch for naught going into CW mode as I tune across the band and
happen across W1AW.
Maybe I've missed something for not being as active as I should be, but
I've yet to hear modulated CW (A2) even once in routine operating.
I have a problem with the ascertation that most Cw these days is MCW and
transmitters can't be managed at 'speed'.
Please clarify this and I promise I'll get myself up to speed.

When you transmit a single tone thru an SSB transmitter, what comes out? An
unmodulated carrier -- you cannot tell on the receiving end whether it is
being done this way or with an oscillator and power amp. There is no
difference! Key the tone, key the carrier, machts nichts.
With FSK you shift between two tones and there is no way to tell on the
receiving end if I am keying tones or keying two rf oscillators. In W1AWs
case, if I push a 750 hz tone thru an SSB transmitter at 7039.25 USB or
7040.75 LSB you cannot tell it from a MOPA at 7040; it is still A1. Think
about it.

I think "they" have changed all these codes on you, fellas (again,
sigh).

The initial "A" designator now applies to double sideband, full carrier
emissions.

I was given a older (circa '92) satellite receiver (working when last used) that has a 950-1450Mhz varactor tuner in it. Questions:

Given the variety of homebrew spectrum analyzers using CATV and UHF varactor tuners, is it possible this 950-1450 Mhz tuner has some promise?

Would it be terribly difficult to use the 70Mhz IF output in such a design without special support chips?

Thanks in advance.

Brian

The 70 MHz is just about where you would want it.

I'd use a simple bandpass filter, followed by an inexpensive
DBM to bring the IF down to the 10.7 MHz range where you
could use cheap ceramic and LC filters to set the bandwidth.

Do you know the LO range, and whether if it is high or low side
injection? You will have to do some modification of the tuner's
frontend, and perhaps the VCO, to get HF/VHF coverage.

Not knowing all of the taps on the transformer, another
possibility is feeding the transformer 125VAC on its
208 primary winding to get approximately half the secondary
voltage. 220VAC is preferred, but if you run a dedicated
30 amp 125VAC feed (to electrical code spec!) just for the amp it should
work.

Anybody have one of these? I picked one up a while back. It is a precision adjustable capacitance box designed for calibrating (military) aircraft fuel gauges. It is a General Radio product containing two massively constructed air variable capacitors and a switched bank of fixed capacitors to add capacitance to one of the variables.

I am trying to determine whether this unit is functioning normally. I would like to compare observations with someone who has a known working unit.

Please respond by e-mail.

Brad

4054. FS: Componants for Sale

I have for sale the following:

Rohm PN2222A's in TO92 case.

50 for $4.50
100 for $8.25
200 for $15.50
500 for $37.00

Also

Chassis/Panel Mount BNC connectors with washers and lock nut.

25 for $12.40
50 for $21.00
100 for $36.00
500 for $138.00

All prices include shipping to anywhere in the USA. I will ship to foreign addresses but please check with me first so I can get you the proper shipping fees. Qty's of 25/50/100 are shipped in padded, reinforced, envelopes. Qty 500 is shipped in a small cardboard shipping carton.

Agreed but with modern balanced mixers 40-50 db is relatively easy and simple-minded. You also get some help by setting the carrier a tad outside the passband of the filter. Having spent a lot of time adjusting carrier balance controls I am happy those days are pretty much over.

It is for that reason, among many others, I am not too happy to see the current crop of rice boxes do Antique Modulation so they can be sold to CBers.

I'm gonna have to go to the books on this and see what has changed. I think we are talking about the same thing, just calling it by different names.
I certainly agree with FSK being sent as 2 individual SSB audio tones, but I'm not on base with the concept of CW being classified as a single audio tone on/off transmission.

I probably should dig further into the thread, but one can get very
different results when feeding an audio oscillator into the mic
jack of a transmitter.

"Modulated CW", which used to be A2, was when a keyed audio oscillator
was fed into the mic jack of an AM transmitter. You'd commonly see
that in cheap walkie talkies for the 27MHz range, when they had a button
on the front for sending code. I'm not so sure how common the mode
was, but you would see it described in articles for use on VHF for
local use (expecially when the US Novice license lost voice privilieges
on 2M, but could still use A1 and A2).

Likewise, what used to be F2 was feeding a keyed audio oscillator
into an FM transmitter. You still see it, with CW ID'ing of repeate5rs.

Either of these give you a full carrier, and you are merely using
a code practice oscillator instead of a microphone to modulate the
transmitter.

Feeding an audio oscillator into an SSB transmitter does of course
give the equivalent of a simple carrier. The proviso is that the
oscillator has to be a clean sine wave, and the balanced modulator

in the transmitter has to be well balanced 9and the unwanted sideband has to be eliminated). If one of these factors is missing, you will get A2 modulation, ie a single tone on a carrier.

Yeah, I think so too. I agree with the substance of what you guys are
saying. I just had to throw in that bit of trivia.

The regs recognize for a whole bunch of ways to generate CW or FSK. The
definitive part of the code for these modes is the third character: an
"A" or "B" (= telegraphy) for CW or "D" (= data transmission) for FSK.
One of the many ways of generating CW is single-sideband, suppressed
carrier with a single channel containing quantized or digital
information on a modulating subcarrier transmitting telegraphy
(designated code J2A). The corresponding designator for FSK generated
by SSB is J2D (I think).

It all seems rather absurd to me.

I checked out the FCC site for the 'new' emission designators. What
used to be so simple is now pretty complicated since they use two
different systems.

Sodium Sulfate ! ? Why not just add Sodium Hydroxide to the Sulphuric acid Electrolyte

2NaOH + H2SO4 = Na2SO4 +2 H2O A saturated solution of NaOH is ~ 10 Normal or 40% W/V add drop-wise to Sulfuric Acid solution with careful stirring, NB both solutions are highly corrosive handle with appropriate care ! and replenish sulfuric acid with about volume equal to that volume of 10N Sodium Hydroxide used !

I have some Misc items FS

Weston Model 302 volt meter: this is a rectifier type volt meter reading from 0-1500 volts. Meter is in good condition and I do have pics. 30.00 OBO + shipping

Weston Model 302 MA meter: This is also a rectifier type meter reading 0-5 MA. This meter is also in good condition and I have pics of this one as well. 30.00OBO + shipping
Both meters are accurate against a DVOM

Adjust-A-Volt Variable auto transformer. is adujustable from 0-165 volts @1.25 amps max. This is a single Phase variable transformer in very good condition. Contacts are intact and in good contition as well. Make me an offer + shipping on this item. Pics of this are also available

I set of brass stand offs.
4 2.50 in (63mm)
2 1.50 in (37mm)
2 .75 in (18mm)
2 .25 in (6mm)
4.00 shipped on these.

The best I saved for last
Electran 117v 50-60cy in and 1000v 25ma transformer. Transformer ohms ok but I was unable to put it under a load. Make me a reasonable offer + shipping on this item. I also have pics of these last 2 items if you wish to see them as to condition

Tried that and I was inundated with messages. Even the daily blob of messages was too much to wade through. I'd rather spend time using the radio than reading about using it. :-)

Doug,

Leave the grid bias as is and switch the screen voltage on thru an additional
contact on the antenna relay.

I use a single form C contact with the transfer or 'fixed' contact connected to
the screen grid, the 'make' contact connected to the screen supply, and the
'break' contact connected to a 100 ohm resistor to ground.

The easiest way is to use an extra contact on the antenna switching relay,
(where you may chose to use a 3PDT instead of a 2PDT relay for that function),
but a separate relay works equally well.

As a safety measure, I also add a 10K resistor from the screen to ground in
case the relay ever makes a bad contact to the 100 ohm resistor.

I have used this method many times with no problems.

When that screen voltage drops to ZERO, that the tube will shut off without
having to make any change to the control grid bias level.

Good luck with your project.

Regards,

Dennis O.

I heard of method to destroy sulphate on plates is modulating charging current with frequency on which its crystal structure resonates. It was designed as "unit" that you connect in series with battery and they recommend constant use of such device to prevent crystals formation.

There was no details in article regarding frequency or any details on method. I tried to ask friend of mine who studied chemistry what frequency may be in question, he asked his college who is assistant ih Physics departement but we did not come up with solution.

Anybody knows some details regarding this.

This has been a lively topic on rec.audio.tubes for some time. If you check carefully, you'll see that their website hasn't been updated since circa April 2000. My understanding, based on postings and e-mails from Eric Barbour, ex-Svetlana application engineer, is that money problems on the American side of the operation have made them close their California office, but their Georgia office (as of several months ago) remains open. The factory in Russia is still in operation, and Canadian and European distributors of Svetlana audio tubes seem to have new stock, but there are hints that some USA distributors of Svetlana audio tubes have had some delivery problems. I do not know the current situation, nor do I know how it affects Svetlana's RF tubes. If anyone reading this has deeper insights or more current knowledge I, and I suspect lots of other people, both here and on rec.audio.tubes, would appreciate hearing about it.

Greetings all:

I am trying to track down information and sources for a Tube made in the US by Varjan, a BTR 160. It's a microwave tube, goes up to 1.3 GHz.

Anyone know of where I can get some information, and perhaps a source of these tubes?

Cheers,

The Duck

Jerko:

There are a few sites on the internet that advertize special pulse chargers that are supposed to do what you've heard about. I don't remember the URLs, but I found them just by doing a Lycos search, so you should be able to find them too.

What they were claiming didn't sound right to me, either. I work in a chemistry lab and have done a bit of study of how to solubilize and precipitate lead in industrial processes and in the environment. I'm no expert on lead-acid batteries, but I just don't believe the pulse charging business. (However, note that those "special" pulse chargers are not to be confused with ordinary chargers that simply turn the current on and off at a low pulse rate. The low-pulse-rate chargers are just trying to keep the battery topped-off without overcharging.)

I do know that gold is never plated directly over copper, because the two will alloy. A barrier, always nickel in my experience, is plated onto the copper first. So you'll have to be able to plate both nickel and gold. Hopefully somebody will be able to tell you how.

I've been investigating this myself for some time. Both Antique Electronics (www.tubesandmore.com) and Caswell Plating (www.caswellplating.com) have small-scale electroplating kits for both gold and nickel. They're intended for repair and restoration work, but I wonder if they'd work in this application as well. I've never gotten around to actually trying this, and I'd be interested in hearing if somebody has any actual experience doing this on homebrew PCBs.

Copper usually makes up the extra material in the various jewellery
gold alloys, 24 karat is pure gold and is very soft with no strength
the more copper, the harder the alloy gets.

Typical jewelry is around 14 carat, or 14/24 = 58% gold. In contrast, a good quality connector has about 100 microinches of gold plated over 1400 microinches of copper (so-called "one ounce" copper), so the ratio is very different even if the two metals aren't intentionally mixed. The purpose of the gold is to prevent oxidatation and other corrosion of the contact surface. If gold is plated directly over copper, the effect is that enough copper migrates to the surface that the contact can corrode. This also sometimes happens when a nickel barrier is porous due to a defective process. I'm not certain, but think this process can occur over time.

That's just about all I know about the topic, learned during a career in electronic product design and development. I was fortunate enough to have real experts available to analyze and solve corrosion and plating problems, so never had to learn more than the basics. Hopefully a real expert can give more complete answers.

>
> The Q signal is shifted 90 degrees in phase counter clockwise from the I
> signal.

Yup. But what the author is calling "quadrature signals" actually differ
by varying amounts depending on phase angle:

"Let's now call our two [exp(j*2*pi*Fo*t)] and [exp(-j*2*pi*Fo*t)] complex
expressions _quadrature signals_."

The way he diagrams the latter expression on the preceding page, I can't
even conceive of a real-world signal that would do what he describes.

He also says that "If you have a single complex number, represented by a
point on the complex plane, multiplying that number by j OR [exp(j*pi/2)]
will result in a new complex number that's rotated 90 degrees counterclockwise
on the complex plane." Now, *that* is quadrature, the way I learned it.
But the two expressions [exp(j*2*pi*Fo*t)] and [exp(-j*2*pi*Fo*t)] that
he calls quadrature do NOT differ by a factor of j, but by j^2.

So basically, neither his diagram nor his math appears (to me) to be
describing quadrature signals, while he's explicitly stating they are.
And I still have no concept of a real signal described by a phasor
rotating clockwise.

The Butternut HF-6V has a coil/inductor at the base (coil Q) which
apparently serves to tune the antenna for 80/75 meters AND to provide
a DC ground.

I like the idea of that static ground. I have a 33-foot "flagpole
vertical" which I use for 40-meters and up; should I expect any
significant tuning change if I add a similar inductor to it?

During the 1986-87 school year I saw several little shops in Nigeria
where car batteries were "reconditioned":
* cut them open at the top,
* remove the plates,
* sort plates according to how good they looked,
* rebuild using the better-looking plates.

They definitely did NOT build new batteries, but this "rebuilding" seemed
to be a thriving industry.

I think the inductance to ground is actually part of the impedance matching. The feedline goes to a tap on that inductor does it not? This is the classic Gamma match. If you want lightning safety, you should have a lightning arrestor in the feedline, tied to a good ground. If you just want to bleed off the static, connect a 2.5Mh RFC from the feedpoint to ground. (There may already be one in your transceiver.)

Note: My comments may be off base in regards to the coil because I am not familiar with the Butternut.

4090. Radio Shack FAQ

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-06 20:56:37 UTC
From: Brian Short <k7on@earthlink.net>
Message-ID: <MPG.15b035eb99f9934a9896c8@news.earthlink.net>
Source record: 51687

Most of us have a Radio Shack pretty close to us. Some of us have stores better then Radio Shack nearby but sometimes the better store is further away (distances vary by location).
Most of us buy last minute parts at Radio Shack, sometimes 5 minutes before closing. Sometimes they have what we need, sometimes not.

Sometimes Radio Shack closes before the posted time - this aggravates us, but we usually still shop there but only if absolutely necessary.
Some of us have witty slogans or monikers for Radio Shack. Some of us get upset when people use witty slogans and monikers.

Some of us don't mind giving our names when making purchases at Radio Shack, some of us do. Some of us make up funny names and use those and some of us think the staff at Radio Shack doesn't get it and this amuses us.
Some of us don't like Radio Shack for one reason or the other.

Some of us think Radio Shack is staffed by morons, while others think they have knowledgeable friendly staff. This surprises us because other retail stores where the staff is paid minimum wage and the manager puts in 60-70 hours a week have much more knowledge employees.
Consensus is the manager at the particular Radio Shack is an important component in the service one receives at Radio Shack.

Some of us remember the "old" Radio Shack and an unnamed but good store nearby. Knowledge of this good, but unnamed store will elevate you highly amongst your pears while newbies will sit back in awe.
Some of us work at Radio Shack and some of us used to work at Radio Shack.

There are at least two and possibly three different "levels" of Radio Shack; Company Store, Privately Owned and Express. (this will be on the test later and the answer will be "D" - all of the above)
Some of us use Radio Shack coupons, some don't. Some of us combine the coupons with other coupons for big savings.

Talk of Radio Shack will bring out cries of Gentlemenship and spawn ill conceived posts about the current ham radio licensing structure and tales of how old licenses are better because the testing was done in front of FCC examiners and you had to scratch schematics into the parking lot using a fork. No, you can never reach the Ham pinnacle that those who performed this feat are at - don't even try.

my rotator has stopped. suppose it is the capacitor - quite stupidly
it is mounted inside the outdoor unit.
wonder if it is possible to remove it without removing the rotator
unit from the tower?

Is it necessary to have the capacitor in the rotator or can it be
mounted inside the control unit as with telex/hy-gain type
controllers?

Hey Bill,

Well seems to me in the good old days those black wrinkle
panels were steel. A real pain in the Arss. Black wrinkle paint
is available at most auto parts stores and the aluminum panels are
much easier to work with. Use krylon 1613 semi flat black for
back side of the panel and shoot the front with any spray can of
wrinkle.(they all seem to work equally bad)

A good hot day in direct afternoon sun will help insure
a good wrinkle on a flat panel when done in black. Case's boxes and
3 dimensional items will require all of the above and a heat gun
and or gas grill. No basis other than my own experience here but
I have noticed that wrinkle only wrinkles when applied to bare
metal. Use a chemical stripper to remove any other paint or primer,
if you have a hunk of bondo or filler in there just standby with
the heat gun for that spot. Heat it from the back and be prepared
to strip it off and do it again if ya need to.

My observations are based on present day materials, I know
most WWII stuff was primed with Zinc Chromate and all that, but all the
paint formulations have changed. Some changes good, some bad. I blame
the bad changes on the EPA and 68% of the population of California,
I credit the good changes to American engineering and intellect.

I have launched a new IPHONE ham conference room page.This site has multiple conference rooms from around the world which you can talk to other hams over thier local repeater links. You must have java enabled and have the Vocaltec software on your puter for the conference rooms to work.You can get the software on the site . For those who are familiar with the system , this web page loads much faster than most others on the net and has all know conference rooms so you dont have to visit multiple sites.Click on the urls below to visit the site, you can also visit my Tampa Bay Radio Page.
Click this url to visit the iphone conference page;

A number of the pro-sound dealers have rack equipment available;
panels, screws, etc. Check with www.partsexpress.com They show
aluminum and steel panels in powder black (not crinkle).

4098. Re: coil to ground at base of quarter-wave vertical?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-07 01:10:51 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <3B46618B.7A2F07F@att.net>
Source record: 51695

The little coil at the base of the HF9V and HF6V is there only to slightly improve the feedliine match on 80 meters. It does NOT tune the antenna on 75/80. It's inductance is highly non-critical. It is not tapped and the feedline connects directly to the base of the antenna right above the insulator between the base and the ground tubing.

Adding such a coil to a plain 40-meter vertical could be expected to have a major effect on its feedpoint impedance.

While it serves an additional purpose of bringing the base of the antenna to an earth ground connection, the same can be accomplished with the Butternut or any similar vertical antenna either with a simple 1 or 2 millihenry r-f choke or with a 10K resistor. None of these values are critical. And neither should affect tuning.

The page does have a diagram of a circuit using an N-channel FET.
It is just not in the pdf for the original article. There is also a
design for 24V systems.

It sounds interesting. There are links to some commentary where
people seem to have had positive results, both in reconditioning
batteries that were dying and in keeping batteries in good shape for
long periods.

May be worth a try. I have no experience yet though.

A roofing filter is generally fairly wide bandpass filter. Its purpose
is 'damage limitation'. For example, for the 40m band, you could have in
front of the receiver a filter which passed all of the band, but
rejected the strong broadcast stations outside the band.

You have a similar situation at I.F. There is often a fairly wide
bandpass circuit (L-C, ceramic, etc) before the highly-selective crystal
filter. It's a general 'cleaner-upper' filter.

I see no reason why an LPF should not also be considered as a roofing
filter.

Ian.

Source record: 51558

Hi Bob,

On a typical 1980's HF radio you do up conversion to the first IF frequency . You have a low pass on the input to the first mixer and a bandpass on the output of the mixer. The first IF is generally in the 45 to 150 MHz range. After the bandpass you down convert to a more rational IF frequency to do the bulk of the filtering and signal processing.

In this scheme of signal processing the bandpass filter in the first IF is called a roofing filter.

Hope this helps.

Source record: 51557

I'm not sure you'll find a definition that everyone will agree to...

I use the term 'roofing filter' to describe a filter that is
wider than the final ultimate bandwidth. For instance, one
might use a inexpensive roofing filter at the first IF frequency
and follow that up with an expensive mechanical filter at the
second IF freqency that is designed to the exact characteristics
of interest (i.e, SSB filter).

You might use a roofing filter to limit noise bandwidth,
attenuate large out-of-band signals, eliminate of spurious
responses etc.

I can imagine the term being applied to any type of filter -
be it bandpass, lowpass, or highpass.

Bob.

> he calls quadrature do NOT differ by a factor of j, but by j^2.

Oops. I knew I should come back and look at this. That's silly. But they
still aren't one multiplied by j (or exp(j*pi/2)) to give the other, so
it seems safe to say they aren't a constant 90 degrees different in phase.

Bill..

Where can I get one of those nifty troll-o-meters? At the moment, I
can't distinguish between genuine postings and trollings.

I wonder if Radio Shack (it's Tandy in the UK, isn't it?) sell them. I
suppose I could actually go in and ask them, but I don't want to make a
fool of myself in front of the experts. It's a question of how you
pronounce it... 'Troll - OH - meter' or 'Troll - omm - etter'.

Why is life so difficult?

Ian.

Check some of the MMDS television antennas. They are around 2.1-2.2
GHz.

As far as I'm concerned, the owner of the web site is a modern Chicken Little, running around shouting that "the sky is falling."

What has really happened is that Windows XP's TCP stack has been brought into congruence with most versions of Unix, with OS X, and even with some versions of MacOS: The user can fill in the fields of IP packets before they are transmitted. Yes, that allows "spoofing", but it has always been possible for most other OSes. The web site mumbles something about DOS or DDOS attacks, but the perps of DDOS attacks don't care about spoofing anyway since they're not using their own machines. So what if the packets get traced? Spoofers have plenty more compromised "zombie" Windows machines where those came from, and getting the owner of a zombie in trouble seems like icing on the cake.

The problem isn't Windows XP -- it's Windows in general. Badly configured "out of the box", Windows 95/98 machines are easily taken over and turned into zombies by means of several well-known security holes. If you go to to http://www.sdesign.com/securitytest with your Windows or Linux or Mac box and pass their checks, you will be among a tiny minority of users who can do so. In fact, that's what you ought to be doing first -- not worrying about Windows XP!

For static discharge, shunt the antenna base to ground with a (low
noise) high value resistor. The 50 ohm system will never notice a
shunt 10K at the antenna.

It's no big deal - any decent firewall will protect an internet client machine from being affected - and if you run an internet web server you can easily protect your server, but there is not a lot you can do to prevent a "denial of service" attack to your ISP connection.

In order to exploit the XP raw socket issue - or conduct any type of malicious activity - a hacker has to be able to obtain access to your machine first.

The only ones who will be affected by the TCPIP protocol layer in XP will be the "computer illiterate", and these types will be open to cyber attack regardless of which OS they run - most of them already allow easy NetBios access to their machines from the web and they don't even know it...

Hello All -

I'm looking for suggestions for potential vendors for a small double sided printed circuit board (approximately 1" x 2") with 40 holes. Initial order quantity would be 100, with potential of future orders.

Anybody have good experiences or bad ones?

Please e-mail me direct.

Thanks

Unless you just want to build one, something like an old CATV FSM can be had for dirt cheap....And you get accuracy within a few db! Here's an example...

Can't hardly go wrong with 6146's. They come in several
varieties (-A, -B, etc) but the differences are minor and all
will work well. Find an ARRL handbook from the '50s or '60s and
you'll have lots of useful AM information. If you can't find one
at your library, eBay usually has several. You can find 6146's
there too.

Have fun.

With all the power you can get from a pair of 811A modulators it might be interesting to build a more powerful RF stage, such as a pair of 813s or at least one of them. That was a popular combination back in the early 1950s.

4140. Re: "decoupling" in af circuits??

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-09 04:05:39 UTC
From: Pete Gianakopoulos <n.gianakopoulos@worldnet.att.net>
Message-ID: <n4a27.10303$Fy3.914780@bgtnsc05-news.ops.worldnet.att.net>
Source record: 51587

Decoupling networks can either be RC or LC networks. It will take the form of a low-pass filter; it will either be a series L shunt C or a series R shunt C. The corner frequency will be determined by the time constant of the RC or LC circuit. If a low value of R is used, a relatively large capacitance will be used, in order to have a low enough corner frequency. In high frequency circuits, there will be a large value cap, in parallel with a small value cap, in order to have good high frequency characteristics. As the other folks stated, the purpose of the decoupling network is to decouple, or disconnect the output of a stage from the power supply rail. The way it does it is in this way: Let's say that you have a transistor amplifier stage. Rc might need to be 4.7K. What you would do is put a 100 Ohm resistor in series with the 4.7K resistor that connects to the supply rail. At the junction of these two resistors, you would connect a bypass capacitor to ground. This does not affect the operation of the device, because the device output is 4.7K away from AC ground. It does, however, prevent the output of the device from modulating the power supply rail.

4141. Re: AM Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-09 04:07:58 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <3B492E0D.AAEF5BA7@att.net>
Source record: 51588

From my AM days in the 40's, a pair of 811's to modulate a couple of 6146's
is pretty severe overkill. We used 811's to modulate 812's running up to
500 watts plate input. That was the basic tube set designed by RCA for
medium-power AM rigs in those days.

Why not consider another pair of 6146's for modulator tubes? Even
triode-connected they should be more than adequate.

True, 811's are overkill, but if BluChunks wants to go real
cheap, they could be used in parallel class A Heising modulation.
Remember that? No modulation transformer, only a choke. I used
Heising modulation on several rigs I built back in the '50s and
it worked great. Of course, if you already have a modulation
transformer, that's a more efficient way to go.

Then that is the real concern. That so many
computer newbies are eazy zombies.

One would tend to think that it would be absurd to spend
so much time fooling around with such things when they
could spend less time making a million dollars honestly.
But there really are people out there with lots of time
on their hands (and doting mommies) that think it would be
real "kewl" to crash a plane, or blow up a building, or deny
service to thousands by tying up systems.

If you threw them all in prison and give them playstations,
they would probably be very happy.

From: Kurt Stocklmeir <kurtstocklmeir@worldnet.att.net>
Message-ID: <01c1089a$86a30160$6c3c4f0c@oemcomputer>
Source record: 51594

Are there any simple methods of creating short pulses of radio waves.

Are there any simple methods of picking a middle frequency for a short pulse since it is probably true the pulse will be made up of many frequencies.

A wave is made up of many frequencies. I may want to decrease the amplitude a little of some frequencies (I know some filters will destroy the whole frequency but I am talking about just decreasing the energy of a frequency a little). Are there any simple methods for this.

A pulse generator creates a short pulse with a middle frequency. The pulse is made up of many frequencies. I am having some trouble seeing what happens. I see a lot of short pulses going through a wire. I guess they change direction after a certain amount of time??? A whole bunch of short pulses go in 1 direction and after a certain amount of time they go in the opposite direction??? I think the pulses change direction a certain number of times each second??? But each frequency that makes up a pulse is changing direction a certain number of times??? I guess there is destructive interference for all the frequencies between the pulses???

Are there any good mail catalogs for parts associated with electric circuits.

Thank you for any answers.

Old ARRL handbooks cover it. All you do is take the B+ line from
the PA which would normally go to the power supply and run it
through a conventional choke (not a "swinging" choke) of about
5-10 henrys. You then connect a class A amplifier of suitable
power output (1/2 the DC input to the PA) so its current also
flows through the choke. That's it. Simple and effective. The
only drawback is the modulator tube or tubes have to run class A,
which is only about 30% efficient compared to push-pull class AB
or B which is about 60%. Class A also has the drawback of
drawing power all the time, not just when you are speaking. For
rigs up to 100 watts or so, the loss of efficiency is not a great
concern. For a KW rig, well, let's just say your shack would
stay nice and warm. :-)

Uhh...I'm not talking about putting one on 160m and the other on
2.1GHz. I'm talking about a few MHz spread, at most. Definitely both
within the range of a single rubberized whip. I can get a 2m HT
smaller than my cigarette pack that will handle a lot more than two
frequencies. At the power levels we're discussing, they wouldn't need
to be more than a few kHz apart, but even with the idea of a CAP
frequency and a MURS frequency, you're not talking wildly different
from a hardware standpoint.

>Since the small clubs & such would have no 121.5 finding equipment or

>lengths, etc.

Rat Shack PRO-Whatever scanner. Mine was $70, and a simple TDOA setup
makes it pretty easy to DF anything it will receive. Remember, the
beacons can't hear, so you don't need to talk to them. 6m, 2m, 440,
MURS, airband, marine VHF, and a lot more falls within the limits of a
really basic scanner.

I should also mention - don't forget when you're modulating
tetrodes such as 6146's, the screen must be modulated too.
Simply take the screen dropping resistor which would normally go
to B+ and tie it to the "top" of the Heising choke. No other
connections necessary. Also, don't use an overly large screen
bypass capacitor or the modulating effect will be lost. A .01
mfd is about the max you should use.

This is true regardless of whether you're using Heising or
conventional plate modulation.

one German suggestion is to use a NAND gate, split the signal into to
parts where one goes direct to the NABD gate, and the second through a
number of gates as noninverter to the other input, it will create a
negative going spike where the length depends on transmission delays
in the noninverting gates

this works fb for harmonic generator (xtal calibrator) and electric
noise simulator

Hi there,

Me again.

I still have some parts left.

Rohm PN2222A's in TO92 case.

50 for $4.50
100 for $8.25
200 for $15.50
500 for $37.00

Also

Chassis/Panel Mount BNC connectors with washers and lock nut.

25 for $12.40
50 for $21.00
100 for $36.00
500 for $138.00

All prices include shipping to anywhere in the USA. I will ship to foreign addresses but please check with me first so I can get you the proper shipping fees. Qty's of 25/50/100 are shipped in padded, reinforced, envelopes. Qty 500 is shipped in a small cardboard shipping carton.

> An omni directional would be better for this purpose, I think.
> There is a webpage about this on:
> http://homepages.wwc.edu/student/kyleti/discone.html

It all depends on what your goals are. If your system is a point-to-multipoint setup (in other words, one access point serving multiple end nodes), directional antennas at the end nodes can be quite appropriate, and extend the range of the wireless LAN significantly. And, obviously, point-to-point links can use directional antennas at both ends.

Many types of antennas, including Yagis, are commercially available for the 2.4 GHz band. They tend to be expensive by ham standards, however. Popular antenna types include omnidirectional fiberglass-covered poles, directional plate-type antennas, and sectorized antennas (corner reflector designs with adjustable wings so the beamwidth can be adjusted); all of these work well for their intended purposes.

My former employer, Broadband2Wireless (a wireless network company, now gone) tested a commercial Yagi for 2.4 GHz, and were not impressed with its performance. It worked well in dry weather, but rain and snow detuned it badly. It might have been suitable for the southwest US, but was a bad choice for Boston.

Besides the ARRL and RSGB microwve books, you might do a Google search on "W1GHZ" and/or "N1BWT." There are also a few links to Paul's pages in my microwave-link article below.

You might try rec.radio.amateur.antenna. Some of the sci.electronics newsgroups might also be helpful.

4163. VHF CW or SSB plans?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-11 05:00:20 UTC
From: "Joe Bramblett, KD5NRH" <joebramblett@drunkenbard.com>
Message-ID: <AC3587FCD0377638.4EA583A04AAEEC07.9DE452554BFD784E@lp.airnews.net>
Source record: 51610

I'm looking for 2m or 6m CW or SSB plans for both transmitters and receivers. Preferably solid state, designed for 9 or 12VDC, small, backpacking type stuff. I'm starting to get interested in homebrew QRP, and CW seems like the best way to go.

Also, any SSB receiver plans for other bands could be handy to have around, as I'll probably be getting my General out of the way soon, and would like to get in some listening time.

ISTR seeing some plans for add-on BFO's for the various cheap SW receivers; I have a Rat Shack one with an aftermarket external antena jack that I'd like to try to add SSB capability to, if anyone can point me to those plans.

Thanks,

Joe Bramblett, KD5NRH

Some expertise may be here.

There are two email reflectors where the most of the microwave
denizens hang out. See:
http://www.wa1mba.org/reflect.htm
and
http://www.ham-radio.com/sbms/reflector.html

You could join and ask again.

As to your actual question, I'd say its probably not that critical.
Best is to bend and taper things at the transition, but if the
dimensions of the smallest end of the horn are close to the WR-42
waveguide size, it will probably work ok without tweaking.

Locate the Kanga USA site- they have a 6M SSB kit. From years on V/U- not much CW (sadly) -except the weak signal gang - so best probably to try a rig that can also do SSB. You might also consider a transverter on a CB rig or on one of the many 10M all modes..

My brother lives about 12 miles from me, but too far away from the CO
to receive DSL or any other high speed internet solution (besides
starband).

So, I was wondering if there was any way to set up a wireless link
between us,
so he could share my DSL connection.

For it to be worth it, I'd need at least a 500kbit connection.

Is this possible with packet radio? I don't think 802.11 would reach,
even with directional antennas.

We live in East Texas, so it's pretty flat here. I'd like to try
rooftop to
rooftop, instead of building towers.

Any ideas? Or, is he stuck with starband?

Let me know,

Dave

Depends which ones you want. Some of them are really easy to find in the catalogs, others impossible. Start with Mouser and Newark. Prices for the coax inserts vary wildly too.

If you're thinking of conventional packet radio terminal applications,
the answer is no.

>We live in East Texas, so it's pretty flat here. I'd like to try
>rooftop to
>rooftop, instead of building towers.

If you have line of sight, you ought to do pretty well. If you don't
have line of site, things get iffy real fast.

>Any ideas? Or, is he stuck with starband?

You must have been reading Bob Cringely's column.

http://www.pbs.org/cringely/pulpit/pulpit20010628.html

You can do this with 47CFR15 spread spectrum radios. However, with
unlicensed applications such as this you'd better be working across a
very rural area. If anything interferes with you, tough. You have NO
recourse. That's what unlicensed operation is all about. There is no
license, but of course, there is no legal protection for your
activity. In fact, if you interfere with any other licensed activity
(such as a ham radio operation), you must cease operation immediately.

Good luck, I hope you find something that works for you.

Try www.6mt.com. You will find all that you are looking for there under the tech lists. Also for the guy who replied and said there is little or no CW operation but from the weak signal guys is sadly mistaken. If you listen onthe 6 mtr band when it ois open there are tons and I mean tons of cw sinals up and down the band even outside the 50.000-50.100 gentlemans agreement band plan. So open up the ears and plug in the keys its there to be worked and fun to boot.
73 and catch ya on the 6 mtr band on cw, psk, phone and HSCW (MS).

It's not unimaginable.

http://www.oreillynet.com/topics/wireless/802.11

http://www.oreillynet.com/pub/a/wireless/2001/05/03/longshot.html

These guys did 5 miles for real, and then calculated the signal loss
that would be seen at a 20-mile range, and re-did the test with an
appropriate attenuator in-line, with good results. Not bad for 31mW.

So long you can get a line-of-site path between you then you can certainly get
802.11 to work over that distance with an external aerial each end :)

> Any leads would be appreciated.
> Don M5AKY
======
Don,Suggest you consider a ten turn potmeter knob/counter combined with a 6:1 coaxial reducer ,used reversed ,hence 1:6 .This gives you 60 revolutions corresponding to 1000 divisions on the potmeter counter or 50 revolutions corresponding to 833 divisions on the counter

The coaxial reducer is available for GBP 2.50 from Mainline Surplus Sales @ Leicester tel:0870-2410810.
The 10 turn potmeter knob/counter is probably available from the same source or from amateur radio fleamarkets/rallies. Try to find a large (approx 40 mm dia)Beckman unit .

Good Luck

Frank gm0csz.kn6wh@ukrs.org located in the north of Scotland

PS : The Beckman knob/counter are often giving 14 indicated revolutions ,hence max.1400 divisions.
With a reversed 3:1 coaxial reducer you then get 14*3 =42 revolutions ,possibly also OK for your application.

The coaxial reducers can also be found on vintage equipment incl that from Heathkit.

Yup!

He should have looked at:

http://www.netnimble.com/products/index.html

15db for $50 is pretty good!

Or if he really wanted the yagi style, hardware store parts for
about $20 and some attention to detail could get about the same.

netnimble also sells a weatherproof access point on that page...
That does *not* include all the functionality of the apple base.

I recall as a child during W.W.II (1940s) in the UK, seeing someone drilling out the intercell connections (which as many of us will recall were then in view on top of the battery, not concealed as they are today) in order to restore one or more cells in a 12 volt lead acid auto battery.
Not sure where 'new' plates or cells would come from in those days of shortage and dependence on Transatlantic convoys (God bless Uncle Sam for keeping us alive anyway!). Possibly they were, as above, just sorting out and using the best plates available. Probably make do and mend situation as they do today in Cuba to keep old vehicles running.
Terry.

We are not, but I have wanted to take the test for a while (I have
that darn
study book somewhere), and I'm sure I can talk him into it. Would we
need
code, or no code? Hmm. . . .gotta read more :)

Is there any way to check and see if line of sight exists, short of
buying a
yagi, and borrowing a spectrum analyzer? Or, would an inexpensive
telescope be
able to see 10 or so miles?

I'm thinking my brother will have to build a little tower to achieve
line of
sight. My house is a 3 story, so I *think* you can see it . . .
unless trees
get in the way . . .

Wow! That is exactly what I wanted to do. What are the 47CFR15's you
are
talking about? Would that direction be better/worse than attempting
to
put Yagis onto 802.11 cards?

And, finally, *is* there a solution without line of sight? Studying
hard and getting a HAM license is definately worth it. (And think of
the cool new toys I'd get to buy/build with my license)!

Thanks again for so many responses, and sorry for the ignorance . . .

Well, Dave, there is an additional factor that will reduce the signal
strengh even if you CAN see his house through a pair of binoculars.

RF signals running parallel to the ground, assuming the antennas are at
ground level, are absorbed by the ground itself. The amount of
attenuation varies depending on the frequency of the radio signal and how
high off the ground the antennas are.

This is an ongoing problem for low power radios such as handhelds and
mobile systems.

Somewhere around here is a computer program I wrote once that calculates
the ground loss among other things, and it was meant to show if one of the
spread spectrum radios My company produced would work in a customer's
application.

I wrote it to be general purpose, and it allows playing with frequency
range, Transmit power, antenna height and antenna gain to see how far the
radio signal will go....

Anyway, I've played with this now and then and a 12 mile link will
require some pretty good antenna elevation at one end, or both would be
better, in order to reduce the ground loss enough to let the system work.

==========

One of the gotcha's in the real world. Even if you have a line-of-sight,
it might not work.

Are you using the Fresnel zone diameter in your program to calculate
the losses close to ground ?

Ideally, the first Fresnel zone should be clear of any obstacles and
since the midpath Fresnel zone diameter at 20 km and 2.45 GHz is 50 m,
at least 25 m below the direct line of sight path should be free of
any obstacles, thus, the antennas at both ends should be at least 25 m
higher than the minimum elevation to get a visual contact.

If standard license free WLAN systems are used and guessing that the
radiation power limit is 500 mW (+27 dBm) EiRP in the USA and a
typical receiver sensitivity of -80 dBm and 125 dB path loss, thus at
least 18 dB of receiver antenna gain is required. A 1 m dish antenna
might be sufficient in ideal conditions, assuming no feed line losses.

802.11 CAN be made to work at that range, if you have line of sight.
Probably not at 11Mbps, though - but even 1Mbps would be fast enough for
your purposes. 802.11FH is a better bet for wide-area links than
802.11b; it withstands interference better. (On the other hand, the
radios are more expensive.)

You'll need high-gain antennas at both ends of the link, and amplifiers
if the radios aren't near the antennas. (Amplifiers are permitted on
unlicensed 802.11 links under certain circumstances, basically to make
up for cable loss on outdoor installations.)

DirecTV dishes can be used for all sorts of amateur microwave projects. You'll have to replace the feedhorn, though, since it's designed for 12GHz, and we don't have a ham band there (though you might give it a try at 10 GHz). For example, an 18" dish, combined with a really good LNA, should have enough gain for the S-band (2.4 GHz) downlink for AO-40. (On the other hand, one of those decommissioned Primestar dishes would be even better, since they're larger...)

Basically, what you've got to work with is a dish, manufactured to quite close tolerances (since it has to work well at 12 GHz). With an appropriate feed, it should be possible to make it work on all ham bands from 1.2 GHz to 10 GHz. It won't have enough gain to be worth the trouble on lower frequencies, and probably isn't made to close enough tolerances to work well on 24 GHz.

An inexpensive telescope ought to be fine. If you can see the other end of the path, that's a good start.

>Wow! That is exactly what I wanted to do. What are the 47CFR15's you >are
>talking about? Would that direction be better/worse than attempting >to
>put Yagis onto 802.11 cards?

Oh boy. This is what I despise about the way unlicensed transceivers are marketed. The reason you don't need a license is because you are afforded no protection from interference. There is no coordination with anyone. It's a cheap "take your chances and see what it does" route. If ANY licensed activity complains about your radio system you must cease operation.

Unfortunately, new spread spectrum technology is being deployed in very high numbers and lots of ignorant marketeers are saying things such as "this unit will work reliably in urban areas" and "it's impossible to interfere with a spread spectrum system". If a vendor tells you that, set BS filters to Full, and go find someone else who really knows the situation.

The details are in the Code of Federal Regulations, Title 47, Part 15 (that's what 47CFR15 means).

>And, finally, *is* there a solution without line of sight? Studying >hard and getting a HAM license is definately worth it. (And think of >the cool new toys I'd get to buy/build with my license)!

At the data rates you seek, the answer is "probably not." I'm not saying it's impossible, just unlikely.

As I recall, yes I am.. It's been awhile. Oh yes, I also add in the insertion loss of the coax for the transmit and receive antennas since 25 meters of coax on each end really hurts at 2.4 GHz.

I had to get the coax insertion loss Vs frequency formulas for a number of types of coax to allow customer selection of how expensive of a coax they are willing to buy.

Now, the nice part of using the actual equation was, I can set it for any frequency and the coax is allowed for. Beats just using x dB per foot for the coax....

I tossed in a factor for earth curvature, and allow for trees, buildings, and such to intrude into it all. It's amazing how quickly this stuff will screw up a long distance line of sight path.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday July 15th 2001
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

They kick some serious butt at 10 GHz. Volume 2 of the ARRL
UHF/Microwave Projects Manual
(http://www.arrl.org/catalog/index.php3?category=VHF%2FUHF%2FMicrowave)
has a great chapter on these.

Depends. What are you transmitting? Wideband FSK and FM video is
relatively tolerant of drift. Voice-bandwidth FM will require
compensation.

You can buy Gunn heaters from http://www.shfmicro.com that will help you
maintain both transceivers at the same temperature.

Look up Motorola. They have lines of communications class PLL chips.

Most consumer electronics (Especially the miniaturized stuff) have the
PLL circuit and a 4 bit microcontroller in one chip (with LCD drivers).

I personally would be a bit leery about running a laptop off of the cars
electrical system. The one time you forget to unplug it when you crank
up might be a disaster. Maybe a charger and spare battery would be
safer?

Linear Tech offers a program to design switching power supplies.

http://www.linear-tech.com/software/

National Semi makes a similar program:

http://www.national.com/appinfo/power/0,1768,383,00.html

I would think other manufacturers have programs as well, but these may easily suit the purpose of making a +13 V to +17 V power supply. I would hang a fairly beefy LC filter on the input to soak up the spike when starting the car.

> electrical system.

Its done all the time. The laptop battery serves to keep things running just fine while starting the engine. Several years ago they made supplies that operated directly from the 12 volt system. Most laptop mfg these days are selling small inverters that covert to 120 VAC and then use their normal AC supply to run the laptop. . You can often pick up the little inverters for $50 or so. One word of warning - these small inverters put out a good deal of RFI so you may want to go for a better unit if you plan on running a ham rig while the computer is running.

4210. Re: 2.4 GHz yagi for wireless LAN

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-14 02:54:14 UTC
From: Jim Pennell <me-nobody@killspam.com>
Message-ID: <9iocaa$79l$1@slb2.atl.mindspring.net>
Source record: 51507

For the ISM frequency ranges which are used for the wireless LAN,
cordless phones, and so on, there is an FCC regulation about the effective
power output and so a gain antenna will almost certainly make the unit
illegal.

It is legal to use a high gain antenna on receiving... Or, if the rig
uses the same antenna for Tx and Rx, the law says the Tx power output has to
be reduced by the antenna gain to keep the radiated power within the law.

To reduce the number of bootleggers, the FCC also mandated using
"non-standard" antenna connectors to keep people from running down to the
corner store and buying a high gain antenna.

==========

All of this adds up to meaning that it'd have to be some sort of hand
made lashup to get the gain and the weird antenna connector.

I can see their point, why the FCC did it this way, they wanted to make
sure it was an even playing field so no single user can have a killer signal
to knock every other user off the air.

Of course, if a user is just out of range for his system, a gain antenna
is mighty tempting....

But if the clown with the high gain antenna blows my cordless phone out
if the water, I'd be unhappy.

I'm very interested in tinkering with direct conversion DSP software radios. I'm looking for a piece of open-source software for Windows that takes I and Q audio inputs from a PC sound card and produces an audio output. I don't want to reinvent this part, I just want to work on DSP algorithms between the input and output. I've been told this is readily done using the DirectSound API in Windows, but I can't figure it out. I'd like to work in VB as much as possible, but C and/or C++ are also acceptable.
Does anyone know of such a piece of open-source software? Has anyone done anything in this area who might share source code?

Thanks,

Joe

Check out Wal-Mart. They have several inverters at reasonable prices. You can get a 30-50W unit for around $10 and a 140W for about $40.

Its the job of the inverter or DC power supply to take care of the spike and not send it on to the computer. I've got over 300 lap-tops in the field which are used regularly in vehicles with an inverter and never had a reported failure due to spikes.

==========
A safe way to use a laptop from the car's electrical supply system is to use an inverter nominally 12 V-DC to 230 or 110 AC. I bought one with a 100 W rating (continuously) for equiv US$ 35.-
Dimensions 5 x 4 x 1.5 inches. In this way you can use the standard AC power supply unit supplied with the laptop.....no hassle when cranking the car engine, there is just a brief AC power cut like a similar situation in the home.
I checked for running the inverter with a HF transceiver and suffered some minor hash.
There is no problem when using FM equipment in the car , ie mobile VHF/UHF , Packet , APRS etc

========
For QRP you just use a single output valve audio amplifier with a
loudspeaker output transformer using the primary winding of that transformer
as a choke eg using the anode voltage of the output valve as the HV supply
voltage to the transmitter's output stage.

About a month ago I had some .1 uF caps for sale and ran out quick.
Unfortunately I didn't make a list of those that wanted them after I ran
out.

I have 450 more now. I wasn't sure if I be getting them again but I found
some more.

How about 50 for $3 or 100 for $5.00 (they're abt 15 cents each from Mouser)
and two stamps? I ship in a 4 by 7 padded envelope.

These are green ceramic disk caps, good for bypass caps I am told. That's
what I have used them for. Marked 104K.

I still have BNC chassis connectors for

25 for $12.40
50 for $21.00
100 for $36.00
500 for $138.00

and I have some PN2222A's left for

50 for $4.50
100 for $8.25
200 for $15.50
500 for $37.00

Let me know if you're interested. All prices are post paid to the USA.

But you can't get 100% modulation with Heising, this way. (Right?)
Can't you use a bypass cap somehow, and reduce the DC input to the final, to provide 100% modulation?

How would the voltage drop to the final plate be calculated, in order to get to this point?

Interesting discussion!
Thanks, guys...
JG

I can understand where a big spike might have come from in the old days
of relay-type regulators, but, in this day of active-device regulators,
someone please tell me what might make such a spike. After all, the
regulator drives the alternator, not the other way around.

Perhaps the starter field disengaging?

And why doesn't that big 60-75 amp-hour battery simply absorb any spikes
that do/might be generated?

And why "60 volt spike"? Why not 20 volts or 40 or 80 or ????

Source record: 51524

From "Voltage Regulators in Automotive Applications" by Robert Pease
(National Semiconductor Corp.):

"There are severe transients on the 12 volt supply at various times.
These are especially likely to occur when a battery is temporarily
disconnected or when the battery terminals become corroded. These
transients, known in the industry as "load dump", can be as large as +60
to 80 volts, for a few hundred milliseconds. Another severe transient,
which usually occurs when the ignition is turned off, can go to -50
volts for 100 milliseconds. This is known as "field decay", as the
excitation in the alternator dies away.

Other transients which can occur at any time can be as big as 200 to 400
volts for a few microseconds, and these transients can go positive,
negative, or both (ac). Needless to say, no ordinary solid-state
circuits can survive this kind of transient without protection."

He outlines a number of other transients and signals commonly found on
automotive ignition systems. I came across this article in National's
1982 Voltage Regulator Handbook. Although pretty old now, I don't see
any reason to think it's not still valid today.

Roy Lewallen, W7EL

While you wouldn't want to connect a lap-top power input directly to the automotive power system without some protection from over-voltage, you can't do that anyway because the lap-top in question requires 17 VDC. You'll need a DC-DC converter or an inverter and a 120 volt AC power supply. Any of these devices properly designed to run from an automotive system will have the required filters to protect themselves and the load from any spikes. The spike protection is not that big of a deal to implement - hams connect mobile rigs to the automotive system all the time.

Assuming you already have a lap-top and an AC charger/adapter, the least expensive way to power it from the vehicle is to purchase a small DC/AC inverter.

Thanks for the links Magne. I found these already, but unfortunately they don't fill my needs. SM5BSZ's work is based on DOS and Linux.....I'd like to get something going on Windows (yes, I've heard about the Windows real-time issues, but I've also heard that people have overcome them). The GNU project is just a shell right now...it doesn't look like anything has been contributed by anyone yet.

I'll keep looking and watching. Meanwhile, thanks again.

That's the right idea. With narrowband voice, it'll be fairly obvious
if your AFC loop isn't working. You can verify your AFC's compensation
range by watching the DC bias change as you hit the Gunn transceiver
with a hair dryer and/or can of freeze spray.

==========
Suggest you get hold of an article in QST - Oct 1990 , pages 18 -21 incl.
" A compact Brick for 6 meters" , a 100 W 6-meter amplifier, employing a
single Motorola MRF492 bipolar power transistor. This part is perhaps a bit
dated ,but there are probably more modern power mosfets suitable for this
service. The power supply for the above bipolar design is 13.8 V.
PTT is derived from the exiter RF output which is rectified , amplified with
an opamp which switches a bipolar transistor which in turn switches the
PTT.

In our area 6 meters is picking up steam!!!!
I've got an old Yaesu 6 meter mobile that i'm running as base rig.

What I would like to due is build a small linear to would take 10 watts in.
Output of say 150 to 200 watts.

I've been combing the web and not finding a whole lot of info on 6 meter
stuff.

Anyone have any info, or know where to get it?

Thanks!!!!

Hi Michael-

This info is dated back from October 1998, so no promises. ;->

Try the nice folks at:

Tower Electronics
Green Bay, Wisconsin

Orders 1-800-662-3422
Tech Info 1-920-435-3359
Fax Line 1-920-435-2980
Email KB9AMM@juno.com

About 4 bucks a piece, 20" long, molded with the following color code:
WHITE - LEFT(Tip)
RED - RIGHT (1st ring)
BROWN - DATA (2nd ring)
BLACK - GND (Sleeve)

Hope this helps,

Randy Barrow

check that discriminator dc output voltage varies less with AFC than
without, it is a good idea to use a tuning meter 'connected' across
the discriminator output to see when you lock on to the received
signal

I recently found one of these at a local electronics shop (You-Do-It
in Needham, MA if you are local). It physically fits just fine, and is
a match for the speaker mike cord. Looks to be some tricky soldering
involved for some of the 4 connectors.

It is made by a company called Calrad.

See at their website: http://www.calrad.com/calrad/cat-59page2.html

Look at parts

30-701 (4 CONDUCTOR 3.5mm PLUG)
30-702 (4 CONDUCTOR 3.5mm RIGHT ANGLE PLUG)
30-700A (4 CONDUCTOR 3.5mm CHASSIS JACK)

There may be other makers, but this is the one I found. The special
connector is apparently used on some newer DVD players and camcorders.

HTH,
Happy trails,
Gary

Gee, this is the first time I've ever seen such a thing at least in
miniature size. Telepnone switchboard plugs look like they have more
than one ring, but I don't think they're found anywhere anymore.

What puzzles me is that Radio Scrap carries the three conductor
miniature plugs and jacks, but not the 3 conductor submini plugs. But
they have 3 cond jacks and 2 cond plugs. I can't understand why they
haven't stocked these for years. They got every kind of adapter, but
just not the submini stereo plugs. It's necesary to drive over to the
local independent electronics store to get them.

Hi Michael-

I have found more current info on Tower Electronics.

3.5 mm 4-conductor, 20 inch long cable, straight plug $11.00 each
3.5 mm 4-conductor, 20 inch long cable, right angle plug $12.00 each

http://www.gbonline.com/~multiplx/wireless/tower/page3.html

It's interesting to see the Calrad and Mouser offerings, but I really
like having the premolded plug already made and the built-in strain
relief doesn't hurt either. Of course, having the proper cable already
on the plug is an extra thing you don't have to go hunting for. ;-)

Later,

Randy Barrow

Does anyone know of any web sites that give pretty good
info or schematics for a tube type dc power supply ?

I have been fooling around with one and two tube radios
for about a year now and would like to have a better
power supply than wiring 9 volt batteries together to
provide power. I would like to build a nice supply using
tubes for rectification and regulation if possible.

Thanks

4252. Re: Using a Yaesu FT-100 with a Linear Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-16 14:48:47 UTC
From: s@9bit.qc.ca
Message-ID: <3b52fd86.12086750@news.9bit.qc.ca>
Source record: 51449

I don't own a sb-200, but Since this is a popular amp along with the
sb-220, I found 2 articles in the subject in old QSTs. There are
maybe others.

See the January 1988 issue page 45 and the May 1989 issue page 48.

Special care is needed to key the SB-200 from a solid state
tranceiver because the open voltage of the open relay on the amp is
-130 V to ground and the relay current can be 50 mA. This is not
compatible with your rig (or many others).

You will need a circuit in between the two, or a relay.

In the May 1989 issue there's a simple circuit involving an IRF9612
power MOSFET.

```
rig o-- 1k res.-- + 9V batt --o--o--IRF9612 grid
control | |
rig o----ground | ---- 470 ohm --- ground
-- zener 15 V/1W ->|--- gnd

IRF9612 drain ---- sb-200 -130V
IRF9612 source -- gnd -- sb-200 gnd
```

note the polarity of the zener.
Hope you can redraw the schematic on a piece of paper.
Hope this will be of some use....

Try looking in any ARRL Amatuer Radio Handbook before 1960 (I live in a small town but we have several from the 50's in the local library). In the fifties they still used the 5UY (I don't think thats the number but it is close) for rectification but by the 60's they where using 1N4007s for the most part. You need a 5 volt ac power tap for the 5UY though, that may be hard to come by unless you can scrounge and old transformer or want to buy a new one (new ones can be expensive). Tube rectifiers have a very nice color when they glow but be careful as they can run *very* hot.

WARNING: This project can be dangerous. Please work carefully, and fully understand the entire thing before you begin. If you blow yourself up from ignorance, I take no responsibility. I am willing to answer questions, so if you have them, ask.

Another approach, with which I have had acceptable results, is to push a high voltage into the battery, but regulating the current to something in the 10-20 hour charge rate. The circuit to do this would be a capacitor wired in series with the AC side of a rectifier. The DC side of the rectifier is connected to the battery, the AC side is connected (through the cap and a fuse) to a wall outlet.

The capacitor size should be 32uF for each 1A of current you want to pass, assuming a 60Hz/120VAC supply. Change the capacitance in inverse proportion to any change in frequency or voltage, i.e. switching to 50Hz would call for 27uF per amp, boosting the voltage to 240V would call for 16uF per amp, doing both would call for 13uF per amp.

Connect a DC voltmeter to the battery. If it is possible, make sure that the electrolyte is topped off in all cells. Work in a well-ventliated area to avoid hydrogen buildup and potential fire/explosion hazard.

Connect the AC. If the battery is badly sulfated, you will see a sharp rise in the voltage at the battery terminals (the ones I was working with hit 98V). You will also hear some bubbling from within the battery (this is why you top off the electrolyte and work in a well-ventilated area). Shortly, (within a couple of minutes of peaking), the voltage will begin to drop again. After a while (don't remember how long it took), the voltage will drop well below the battery's rated voltage, (mine dropped down to 5V) and then will start to rise again. At this point, you can either continue to charge with this circuit (stop it when it hits 14V or so), or you can connect it to a more conventional charger.

When you disconnect the device, you will want to be cautious about touching the line cord plug. It will probably have a high DC voltage on it. Allow some time for any hydrogen vapour to dissipate, then short the capacitors, preferably through a resistor.

Whatever you do, keep your eyes on the voltmeter.

Some tips:

- You may want to heatsink the rectifier bridge. I used a heatsink/fan combo from a '486 PC and it kept it nice and cool. If you do this, use a separate power supply for the fan, as the high voltage will likely burn the fan out.

- Do not use a nonpolar electrolytic cap for this task--it doesn't have
enough heat-dissipation capability. Get an older-style oil-filled cap.
It is a lot larger, but it isn't going to blow up on you.

- Keep kids and pets far away from this thing. The last thing you need is
a loved one drawing an arc off of your battery charger.

I did this project using a set of four 55uF oil-filled caps and a group of
four 90Ah Gel bateries. The results were excellent.

Antenna gain is not restricted under part 15 as far as I'm aware -- only
ERP.

It would be pretty stupid to regulate antenna gain, since higher antenna
gain makes interference to other users LESS likely.

Hi Gang,
I'm working on an antenna tuner design while I'm at my vacation cabin in the Montana mountains, and forgot to bring the software CD with me from my ARRL Antenna Manual. I need the program called AAT.EXE ("automatic antenna tuner"), and wonder if somebody could email it to me (attached as a file, zipped or not). I've got a week's vacation left, and hope to use the free time productively. Thanks very much.

You're right. However, since most of the available wireless LAN equipment has a fixed power output, it puts an effective ceiling on the amount of antenna gain you can use. The limit is quite high, however, since the ERP limit is higher when directional antennas are used; you can legally attach 24dBi antennas to at least some wireless LAN gear, and you can even use amplifiers under some circumstances (mostly when the wireless LAN gear is far away from the antenna, so you have lots of cable loss to make up for).

There is quite a bit of gear made for this use; alas, none of it is cheap. A couple of manufacturers (I happen to know of these because my former employer used them):

Andrew Corporation: http://www.andrew.com - makes just about everything
Til-Tek: http://www.tiltek.com - makes antennas

By the way, I noticed a couple of not-horribly-expensive Yagi antennas for 2.4 GHz in the HRO catalog. They're selling them as 2400 MHz ATV antennas, but they should also work for LANs. They have a 15.5 dBi model for $200 and a 21 dBi model for $230, as well as a 15 dBi omni antenna for $200. They're on page 94.

4262. input impedance for tubes

Yes, but the way the rules were applied on the commercial product my company made, the transmitter was +30 dBm and the antenna was +6 dBi gain maximum for a total ERP of +36 dBm which was the legal limit.

So, if we wanted a higher gain antenna to help the Rx path gain, to comply with the FCC rules we had to reduce the Tx power to keep the ERP at +36 dBm Max.

Assuming it was being used as a Tx/Rx antenna, and since most transmitters didn't lend themselves to programmable power output, that meant the antenna gain WAS restricted by law.

If it had a separate Rx antenna then you could use as high of a gain antenna as you might wish.... So, the non-standard antenna connectors were required on only the transmit antenna connector.

==========

Now, I suspect quite a few of the products out there offer high gain antennas with the disclaimer that "In order to comply with FCC regulations, the transmit power must be reduced"

And, of course, most end users won't even read the disclaimer, much less reduce the Tx power. So I imagine quite a lot of systems are illegal and nobody cares too much as long as they don't interfere with others.

My original point was why it might be difficult to find a high gain antenna that can be connected to a system, and how this mess came about in the first place.

There's quite a lot of the rules for the ISM band products that are downright weird, and I had to fight many of them when I applied for type acceptance on the first frequency hoppers that the FCC had ever seen under these rules.

Fortunately, I am not doing that any more but it was an interesting time.

The rules (15.247) are very specific (and somewhat cryptic).

Oh yeah, before we go any further, all of this stuff only applies to spread spectrum devices!!!

The first thing you have to do is watch the ERP and EIRP along with the dBm, dBd, and dBi. The last one, dBi, can get you into trouble. dBi is referenced to an Isotropic antenna or "perfect radiator", that does not exist. However, a dipole dBd, which to most of us is a basic antenna, has 2.1dB gain compared to an Isotropic. Power is still dBm, but it gets muddied in the rules because of the constant references to EIRP and dBi.

So forget watts and RX microvolts altogether for this stuff, and stick with the decibel all the way around. If you are really hung up on watts, do it after all the calculations. :-)

Basically, in an omni configuration, the FCC limit is +30 EIRP, which is a little more than half a watt ERP.

In a point - multipoint configuration, where a common site is feeding many remote points, the remote units are allowed up to +36 EIRP if they employ a directional antenna. Basically, the FCC gives you a little more because you are focusing your signal.

It is important to note, that in the above scenarios, the FCC limits the power fed to the "intentional radiator" to +30dBm. The EIRP restriction obviously makes this allowable only with a 0dBi gain antenna, or in the latter case above 6dBi gain antenna.

Now, there is one wonderful loophole remaining for point to point links. That is as follows:

Start with the maximum allowable power at the "intentional radiator" (a.k.a. antenna input) of +30dBm. For every 3dB of antenna gain, over 6dBi, take away 1dB of allowable power to the "intentional radiator". Again, the FCC is providing more to the user for the increased focus of the antenna.

With this last scenario, it is possible, with higher gain antennas (+20dBi Parabolas), to use an off the shelf WLAN transceiver with a typical output power of 100mW (+20dBm), and achieve some pretty high EIRP/ERP that is completely legal.

Point 2 Point (ONLY) e.g. both antennas are directional.
Example: (and I am incorrectly assuming no transmission line loss. Hey, its an example!)

+30dBm power to the intentional radiator with +6dBi gain, EIRP= +36
+29dBm power to the intentional radiator with +9dBi gain. EIRP= +38 (ooh, 2

more dB!)
+28dBm power to the intentional radiator with +12dBi gain. EIRP= +40
(starting to get the picture?)
+27dBm power to the intentional radiator with +15dBi gain. EIRP= +42
(Theoretical limit for a high power off shelf unit)
+26dBm power to the intentional radiator with +18dBi gain. EIRP= +44
(Starting to really get good!)
+25dBm power to the intentional radiator with +21dBi gain. EIRP= +46
+24dBm power to the intentional radiator with +24dBi gain. EIRP= +48 (need I
continue?)

Typical RX thresholds are between -77 and -87dBm for a quality link.
Remember antenna gain works both ways!

As can be seen above, the higher power off the shelf models 500mW (+27dBm)
are, ironically, less desirable because you will reach the legal limit
sooner with less antenna gain, whereas a lower power unit will allow a
higher gain antenna (tightly focused beam), providing a better quality link.

However, 2.4GHz is microwave, and subject to the same problems as any other
microwave system. Therefore, before you start thinking about making that 5
to 15 mile hop between your place and your buddy, consider this.

You will still need to do a proper path analyses for a 2.4GHz point to point
link, and even if you can meet all of those requirements, remember that
these are still part 15 devices. If you cause interference to ANYBODY,
including the existing amateur service at 2.4GHz, you must cease operation.
This has already happened in California, where a WLAN based network provided
was ordered to shutdown operation because the system interfered with
licensed amateur operations, which have priority.

Now, I know what some might be thinking. "If I am a HAM, then I can continue
to operate as a primary service". Wrong! Not unless you want to use a
modulation scheme that is legal for the service, and oh yeah, that pesky 10
minute ID requirement. Kind of blows away the whole WLAN idea now doesn't
it? ;-)

Yes, these things are wonderful and getting cheaper. Will they replace
terrestrial microwave?, not likely. However, they do have a lot of
excellent possibilities for both amateurs and non-amateurs. I could easily
see, with some coordinated effort, these devices being used to create a
regional area wireless network backbone, something akin to packet (only lots
better), no small effort there, but possible.

The speeds are getting up there too. 10Mbps is available today, which
provides about 5Mbps usable throughput after overhead, sometimes better,
sometimes worse. Still, even the older 1.6 and 2.0 Mbps devices provide
reasonable throughput that would rival ISDN or cable.

Food for thought in any case!

4267. Need FET info, low input capacitance

Newsgroup: rec.radio.amateur.homebrew

Looking for info on J-FET (field effect transistors) that have very low input capacitance...gate to drain and source. I need a device that has < 1 pF input C and will oscillate in the 0.5 to 20 Mhz range, noise floor is not important. Voltages are 5 to 10 or so, low power, high impedance application.

I have been using the 2N5486 but it's input C is 7 pf and is not working out well in my application. I have heard that UHF FETs tend to have much lower input C. I suppose that transconductance (or whatever it is for FETs) similar to the 2N5486 would be ok.
Thanks
Bob

Bob,

Can't you simply use a 1 picofarad input coupling cap. with your existing
J-FET?

If the input capacitance is 7 pf and you use a 1 pf coupling cap you should get
about 1/8 th of the original input voltage coupled to the gate, but if you have
adequate circuit gain then everything will still work fine.

Oscillators only require an overall circuit gain of 1 at a phase angle of 180
degrees.

Regards,

Dennis O.

Hi Bill,

Is the tube running in grounded grid or grounded cathode ?

I suspect it's grounded grid, in which case the plate RF current is
running through the cathode. In that case you have the RF driving
voltage / RF plate current = input impedance (more or less).

You could start by looking in just about any ARRL Handbook published since
the dawn of creation. :) Your local public should have a few issues on the shelf.

Most crystal calibrators are built for 100 KHz operation. Usually the ones built into receivers are of this type and are not switchable to any other resolution. A nice schematic of such a unit is at:

Build A 100Khz Crystal Calibrator

http://www.rason.org/Projects/calibrat/calibrat.htm

But, that doesn't mean this is the only kind of calibrator. You can start out with a crystal that is much higher and then divide it down. I have one at home that I built over 20 years ago that uses a 1 MHz crystal and is followed by a couple of SN7490 counter chips to give me 1 MHz, 500 KHz, 100 KHz, etc. markers. Of course this can be done with more up to date chips than that but I can zero beat it with WWV and depend on the divided markers to be right on frequency.

You will probably find that getting a crystal for 1 or 2 MHz, and then dividing down, will be cheaper than purchasing a 100 KHz crystal. The 100 KHz crystals usually cost much more than other crystals.

4279. How do I recieve 900mhz stereo??

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-18 17:44:30 UTC
From: Mario <mm@mm.com>
Message-ID: <9j4htu$9n0@dispatch.concentric.net>
Source record: 51475

I have a device called a Soncibox IMTuner which broadcasts stereo sound from my computer to a reciever hooked up to my stereo. I would like to have multiple recievers but they don't sell them seperately. What can I make/modify to recieve this 900mhz stereo signal.

The people at SonicBox said that many 900mhz devices can pick it up like wireless speakers and the such. But I don't want to spend alot of money. I was hoping that there is a 900mhz reciever kit I could build, or plans for a homemade 900mhz -> to 90mhz down converter. But I have been unable to find much usefull information since this is a legally sketchy range.

Does anybody know where I could find some information to do this?? I have an old moded scanner (or maybe it is so old it didn't have to be modded) but I was hoping for a stereo solution.

Thanks,

mario

There is nothing illegal whatsoever about recieving 900 Mhz.
(it's the cel-phone freqquencies int the 800-900Mhz range
that are the hot potato)

What I'd do first is see if it transmits each channel discretely,
modulates each channels as a subcarrier on a main carrier, multiplexes
it like
regular FM stereo.

You might be able to find something used on E-bay, or if you are brave
enough,
hack a cel phone to provide frequencies to downconvert to something
easier to
process, suh as the 90 Mhz range.

Start with a 1 Mhz crystal clock, a very common computer item.
Divide it by 10 using 1/2 of a 74HC390 for 100 KHz,
and again using the other half for 10 KHz. etc.

A 2N4416 would do the trick; the input C is typically 4pF. Another device
that would do the trick is a J310; this device makes a great oscillator,
probably better than the 4416.

From: Ralph Mowery <rmowery@dialpoint.net>
Message-ID: <3B5634FF.84D4867D@dialpoint.net>
Source record: 51482

Because the antenna is usually a low impedance and it is connected to
the low impedance point on the coil of a tuned circuit. If it was
connected to the top of the coil it would load down the higher impedance
of the tuned circuit and the selectivity would be very broad. Usually
the opposit if what is desired.

Even in the simplest receiver circuits, the antenna input signal is commonly coupled inductively to the first (tuned circuit) stage of the receiver.

I.e., the antenna goes to a coil, the opposite end of which is grounded, and the signal is coupled to the initial tuned circuit's L.

Why is it coupled in this manner? Why not connect the antenna input directly to the parallel tuned circuit??

Could someone please offer an explanation? Many thanks!

I have no idea; I haven't checked the site in a couple of months.

However, the ISP where the website is, http://www.fix.net
has a message dated July 16th about some technical problems,
including disappeared webpages. It says that "90% should be
restored by now". Perhaps that's where the problem lies.

Otherwise, one could hope that the webpage has merely changed
locations, and it simply hasn't shown up in the searchengines
yet (I just checked with yahoo, and it showed the old URL, which
gives a 404 error).

Dan's was around long before he had a webpage, so one might
contact him by mail. I don't happen to have the address, though.

4288. Attaching external antenna to wireless home LAN?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-19 04:22:15 UTC
From: jacques_bouchard@yahoo.com
Message-ID: <Xns90E33BF3BAF3jacquesbouchardyahoo@216.187.106.195>
Source record: 51488

This was originally posted on alt.internet.wireless and rec.radio.amateur.antenna, but I received no reply so I thought I'd try this group instead.

A picture of the equipment referred to below can be found at http://www.geocities.com/sniveling_coward_ca/anypoint.jpg

I have an Intel Anypoint wireless network at home (1.6mbps, 2.4GHz HomeRF). It consists of one USB device for my desktop, and one PC card for my laptop. The USB device has an internal antenna that's in fact a pattern etched directly on the circuit board; the PC card has a rubber-coated antenna connected to the card by a metal (copper or brass) bracket.

The range is 150 feet, which in theory should be sufficient for me to work outside on the patio. However, on some days I can lose the connection even if I'm in the next room. I've looked into extending my reach (or at least improving reception and transmission) by attaching an external antenna, but I'm going blindly about this. I know that antennae are a science onto themselves, and while I can work a soldering iron pretty good I know next to nothing about this technology.

I tried clipping a regular stereo antenna (the long plastic T-shape flat cable that pins to a wall) onto the etched antenna without noticeable improvement. I did notice, however, a tiny female TNC-like connector on the board. A continuity test reveals that it's connected to the etched antenna, so I'm thinking it might make a suitable connector.

The PC card has a rubber-coated antenna that connects to the card through a metal bracket that could serve as connecting point.

All I need to know is what type of antenna would be suitable, and what connection point would be preferrable. Naturally, I'm looking for inexpensive alternatives, since this is a relatively inexpensive - albeit suitable - network. I've visited several sites explaining the fabrication process for different types of antennae, but I wouldn't know which model is suitable for my needs.

Thanks for your help.

Source record: 51483

The basic reason for using inductive coupling is to allow matching the antenna impedence to the input tuned circuit. the antenna impedence is quite low (50-100 ohms) compared to the tuned circuit impedence (several 1000 ohms). Receivers sometimes have a second input antenna connector connected directly to the input tuned circuit for connecting short antennas that have high impedences.
Hope this helps
Ralph

Source record: 51484
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.swap

I am trying to troubleshoot a MLA2500 with a schematic from
a MLA2500B and there must be some differences in the control
circuitry. I get about 1500 volts as soon as the amp is powered
on. When the time delay relay kicks on the voltage rises to about
2200 volts. Fortunately I don't have any tubes in the amplifier
to get ruined because to the early HV. Either electronic or printed
schematic would be helpful.

Thanks in advance

Doug N4IJ

==========
If available a variac (variable auto-transformer) would be a safer set-up.

Just add a rectifier diode or bridge, connect battery and monitor battery
voltage and charging current.
Gently increase voltage until current starts flowing and then keep current
down to less than 0.1 C (being 4.5 A for a 45 Ah battery)v by reducing
voltage until voltage has been reduced to approx.14.5 V .
Then allow battery to be charged by a normal charger.
If the variac is for a lower amp rating ,keep the charging current to this
lower rate until battery voltage permits charging on a normal charger.

Thanks also from me regarding URLs.

Although somebody may think this is silly issue, for tube amplifiers
such supply (with good inductor) is must. It is simply not it without!

The copper penny story is almost certainly true. I used to make some very respectable detectors when I was a kid by taking two pieces of copper bell wire and roasting one in a gas pilot light until it turned black. I then twisted it until the outer black stuff fell off leaving a reddish oxide. I then took the other wire and scraped it clean and twisted the two together. It worked as good as a regular crystal diode for me. I tried a lot of other stuff but this was the easiest and always worked and didn't need adjustment.

I'm looking for information on primitive homemade radios. A few of us in the office have been talking about how to build a radio (or a diode) from stuff around the house?

It all started with a story about POWs building radios using a corroded copper penny for a diode? I don't know if that's true either. I have also heard that a razor blade could be used like a cats whisker. Any body really know anything about this? Not much turns up when searching the information goat path.

All feedback appreciated.

I pulled this square peg (octal based, more accurately) out of a Hy Gain 644
"Footwarmer". It was marked "HyGain 760002". I was told that it's an 8908.
Both tubes have suffered a "smoke leak" (vacuum leak) and need replacing.
None of my manuals give the specs for this tube. I would like to find a
less expensive substitute.
Does anyone have it in any of their books?

The razor blade part works. When I was 11 I built a crystal radio
with a razor blade, crystal earphone, a disk capacitor (around 200 pF)
and a coil of enameled wire which I tuned with a slider. The razor
blade used a stub of pencil and a paper clip to turn in to a detector.
It worked, but frankly a good point contact germanium diode would
outperform it.

Have you tried contacting the maker? I have seen similar equiment from Cisco system, so I know that what you are talking about exists. In the application I saw, the antenna was similar to the antenna seen on most new amateur radio hand held radios. I would have to assume that it was set for a specific frequency, tho.

> Does anyone have it in any of their books?

There is NO direct replacement that I know of.

Maco, (a CB linear manufacturer in the 70's), worked with GE to put that tube into a compactron based package called the M-2057. (later called the Y-2057).

The M in the tube designation stood for MACO. (MAjestic COmmunications Co, Memphis, Tn.)

The closest match to an existing tube with an octal base is the 6LW6, but the filament voltage is different, the transconductance figures are less, the capacitance numbers are different, and I believe the base pin outs are different.

If I remember correctly, that Hygain Footwarmer was a grid driven amplifier and I had to change it's input and output tuning to match the pair of 6LW6 tubes.

The original tubes had their filaments connected in parallel, and you have to connect them in series in order to use the pair of 6LW6's

The 6LW6 CAN be made to work as a sub. in that amp. because I have done it; but that was long ago, and I don't trust the accuracy of my memory enough to provide any greater detail.

I hope the limited amount of information that I was able to provide will be of some use to you.

Regards,

Dennis O.

The Anypoint Wireless equipment is that type of equipment that
manufacturers - in this case Intel - hate to offer support on, because
they're working on something better. On the Intel wireless newsgroup, they
refuse to answer questions, referring users instead to their web site,
which isn't very comprehensive.

Since there is no outside connection for an external antenna, I doubt
Intel makes them available. I did see an internel connector however, for
which I may fashion a mini TNC connector. My only question remains the type
of antenna I should build (since buying one would be almost as expensive as
the cost of the unit). From what I've read, an omni-directional antenna
rated at 2.4 GHz might do the trick.

Hello all
I live in an apartment building and have some restrictions on what I can put up.
I want to build a vertical antenna for 10, 12, 15, 17, and 20. I was thinking of just using some tubing to be cut to be resonant on 20m, add some wire radials at the bottom, and use an auto antenna tuner to tune it. Now, the only thing is that the only place I would have to put this antenna is to attach it with arms to our mast running up the side of the chimney. My question(s) is: 1: Would the chimney interfere with the antennas preformance? 2: At the top of the mast are some beams which would be about 5 feet above the vertical antenna. Would these interfere with the tuning of the vertical? Any other ideas on a vertical antenna to build for the bands I mentioned? The antenna has to be under 20 feet tall and no radials, counterpoise, or whatever sticking out over the edge of the roof. Would any commerically made antenna fit these needs??
Please email me direct at: N9RK@aol.com

Greetings. Thanks for looking at this.

I have a piece of equipment that has what looks like an overgrown Centronics connector. It has a rectangular housing, 24 contacts and a pitch of just under 0.2 inches. It is used to connect the plugins to the mainframe of the 140 series of HP spectrum analyzers and oscilloscopes. I need to find some of these.

I have been unable to find a source after an extensive search with the usual vendors and manufacturers. I know that HP made some of their own and that Amphenol once made a compatible connector. I don't even know the name of the connector series. It would be a great help someone could tell me the name of what I'm looking for. It would put me in bliss if someone could sell me one too.

Thanks,

John

Thanks for this infomation. It isn't much, but it's a start.
Unfortunately, my books don't cover the 6LW6 either.
If you replaced them with the 6LW6 and rewired the filaments in series, that should tell me the 8908 is a 12 volt tube.
8908s are available through RF Parts for $100 each. I really don't think this old CB amp is worth dumping $200 into.

I think I might be better off to salvage the parts for a future project using 811As or some other currently produced tube.

4306. faulty LM723 regulator in power supply?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-20 13:32:23 UTC
From: lgagnon@sherrittoil.com
Message-ID: <1d3b4598.0107200532.35ec76de@posting.google.com>
Source record: 51404

Hello. I am attempting to repair a power supply for a Wavetek 3001 signal generator. The supply provides +18, -18, +27 and +7.3volts DC. The +18 volt line supply is based around an LM723 regulator feeding an NPN series pass power transistor. The -18 volt line is derived from the +18 volt line using an op-amp comparing against ground. The +7.3 volt line is pre-regulated only and uses the other side of MC1458 op amp plus a series pass transistor. It feeds LM7805 regulators throughout the unit so I am not to worried about it.

The symptoms are difficult to adjust to +18 volts, drifting at no load, drop from 18volts to 8 volts when loaded with resistive 1 amp. These symptoms suggest to me that the LM723 regulator is faulty. Because there is power out on each line I doubt it has anything to do with the pass transistors or any pre-regulation transistor. How would I go about checking the LM723 before simply replacing it?? The reason I don't want to just replace and try is that it is a LM723H TO-100 can type and I am only able to obtain the DIP14 package so I will have to retrofit!

Voltages at the LM723 appear reasonable, with 6.3v at the Vref....any ideas out there would be greatly appreciated. Larry Gagnon VE6MK

These connectors are now manufactured by WPI and available from Newark Electronics. 1 800-463-9275 WPI makes a number of Amphenols old connectors. The ones you looking for are called "26 Series" 24 pin plug with polarization pins is about $35 24 pin polarization receptacle is $40.

But I believe there is another option to match a low impedance antenna to a high Q input circuit : the capacitive coupling. Instead a tap on the coil, we can make a tap between two capacitors. The tap is connected to the antenna and the ratio between the two capacitors determines the input impedance.

However I think Inductive coupling is often prefered, because it provides a return path for DC and other atmospherics currents.

Thank you for your comments on my point of view.

Jean-Fran&#65533;ois FOURCADIER

"Ralph Lane" <crlane@erols.com> a &#65533;crit dans le message news: 3B5671A1.D23E4EB4@erols.com...
The basic reason for using inductive coupling is to allow matching the antenna
impedence to the input tuned circuit. the antenna impedence is quite low (50-100
ohms) compared to the tuned circuit impedence (several 1000 ohms). Receivers
sometimes have a second input antenna connector connected directly to the input
tuned circuit for connecting short antennas that have high impedences.
Hope this helps
Ralph

You can also try to salvage a 10.0 or 12.8 MHz TCXO from a discarded synthesized VHF radio. The frequency stability will be certainly far better than that you'd get with computer crystals.

(Obviously it's not possible to get in a simple way a 1 MHz output with a 12.8 or 10.7 MHz oscillator, but you can consider this solution considering your precise needs). Other frequencies are OK.

Believe it or not, the boyscout handbook still has a xtal radio design using, I think, a safety ping and some raw germanium and/or equivalent detector piece etc..

I also have heard about using a rusty razor blade.

PBS had a special about POWs. One of the things that was talked about revolved around the POWs using all sorts of stuff to make simple rcvrs to keep up on the outside world.

Sorry, cannot remember the specifics of the show.

I had several requests for the PN2222A's that I had to turn down because I ran out. I now have more in stock, these are Fairchild PN2222A's.

If interested let me know...and I still have BNC's if you are interested:

Fairchild PN2222A's in TO92 case.

50 for $4.50
100 for $8.25
200 for $15.50
500 for $37.00

Also

Chassis/Panel Mount BNC connectors with washers and lock nut.

25 for $12.40
50 for $21.00
100 for $36.00
500 for $138.00

All prices include shipping to anywhere in the USA. I will ship to foreign addresses but please check with me first so I can get you the proper shipping fees. Qty's of 25/50/100 are shipped in padded, reinforced, envelopes. Qty 500 is shipped in a small cardboard shipping carton.

4315. Wire antenna info needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-20 23:51:17 UTC
From: n9rk@aol.com

Source record: 51413

I would like to work 20 m and up and I am still kicking around ideas for an antenna. Does anyone have a good idea for some sort of wire antenna that can be strung between 2 chimneys that are approx 75 - 90 feet apart? Dipoles are out of the question as there would be nothing for support in the center. A coax fed antenna would be prefered but any ideas welcome! Please email me at:
N9RK@aol.com

Hi there,

I actually have the GE data sheet for that tube, but you won't find them cheap or easy. Best to retrofit the amplifier with some 811a types and get on with your life. I've only seen two or three mfgrs use that tube and it's physical large so I just installed a pair of 811a's and they work fine when set for the proper zsac.

cheers

Mark

4318. Frequency Counter Kit

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-21 00:16:35 UTC
From: Dan Tayloe <dtayloe@home.com>
Message-ID: <3B58C9E1.B038CC89@home.com>
Source record: 51416

Our club is offering an inexpensive frequency counter kit for sale.

The stock counter is good to over 75 MHz, and with a minor parts substitution (a 74AC00), is typically good to over 150 MHz with a rf sensitivity of less than 100 mV, typically 10 mV at 7 MHz.

The kit is designed to fit in an Altoids mint tin which it uses as an acoustical resonator for the frequency readout.... which is in morse code. It also makes a great cw "numbers" trainer!

The kit is $20 which includes shipping. This is a very inexpensive way to pick up a nice piece of test equipment to help in building homebrew gear.

Further information including pictures, specifications, and ordering can be found at:

http://www.extremezone.com/~nk7m/cwafc.htm

and on Bob Hightower's website:

http://www.extremezone.com/~nk7m/

Bob is handling this. His email address is: nk7m@extremezone.com

I would be interested in seeing that data.
And, that is the plan I'm leaning more toward. 811As look very appealing at 17.50 each rather than $100.
I would be very interested in a homebrew project involving four 811As that has been written more recently than 1970.
I think the earliest design I have was published in QST in 1960.

I have heard the story of the copper oxide and copper diode, also
have heard of using a bowl of lemon juice with a cats whisker as a detector,
heard the US Navy used this in the early days.

I myself have used flame rectification by heating a 3/16 diameter
rod in a flame to detect with, got poor results but it did work.

So did you TEST the drive voltages to the series pass and driver?
When you have 8 volts out, what is the base voltage of the series pass?
what is the base voltage of the driver?
These tell the story much better than just replacing the chip.

4325. one tube radio receiver?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-21 02:07:01 UTC
From: rhn@nicholson.com
Message-ID: <9jao45$e0e$1@samba.rahul.net>
Source record: 51422

Long ago, I built a couple of one tube radio receivers (one was a radioshack perfboard kit), now lost with all the junk thrown out from the parents attic. I seem to remember them using 2 batteries, a variable cap, inductor, about a half dozen other passive components, a switch, and earphones.

Are there any online documents, or books still in print, which might have a schematic of some simple one tube radio receivers. I'd like to build one again to show what electronics looked like before devices with merely a million transistors were considered obsolete thowaways.

I also remember building a 3 tube kit regenerative (Lafayette?), where 1 tube was the rectifier and another the audio amp.

Thanks!

4327. Flyback transformers

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-21 02:55:18 UTC
From: caveteursus@aol.com
Message-ID: <20010720225518.15478.00000331@ng-fl1.aol.com>
Source record: 51424

I was looking through the 2001 Handbook chapter on power supplies interested in winding a flyback transformer for a +/- 24V 5a (peak) switching supply, probably running ~50kHz. Does anyone have any links to a source for "winding your own"?

The 2001 ARRL Handbook does have a few paragraphs, I'm looking for more sources.

I've succesfully built the supply using a boost/boost inverter with their separate inductors, but was looking to save some real estate.

Hello.

I'd like to set up my own local coverage repeater for some hams in my area...preferably something cheap (under $500) and try to use as much of my own stuff as possible. I currently have a Yaesu VX-5R and dual band 144/440 gain antenna and feedline that I could use, along with power supplies. I'd like to set up the repeater on UHF, in-band.

What do I need?
Is it that expensive to set up a local coverage UHF repeater?

73s,

Jim

Gee, it'd be fun to design a regenerative one tuber! I have built them and they are very simple and easy.

Parallel tuned circuit from grid to ground (with about a 1 Meg in series with the grid, 100 pF in parallel with it). Cathode or one side of filament to ground. Plate to tickler coil on tuned circuit, thence to headphones with bypass capacitor and positive of B battery.

Regeneration rheostat in parallel with tickler coil. Another winding on the tuned circuit to go to antenna.

Battery to light the filament. Power switch need only be in filament battery.

Tube to use, well almost any triode. The common one in the old days was the 01-A, also known as the 201-A and a few other ways. Another good one was the type 30. If you want to use more modern tubes, there were a few like 1H5Gt and so on.

As a matter of fact, when I was in college and my gf in high school, her project was just such a radio. I designed and built it for her, got it working, then tore it apart so she could build it in class. It worked, and the teacher was positively flabbergasted!

As a footnote to all the above, I recently discovered that I STILL HAVE THIS RADIO. It was built on a piece of wood. Used Fahnstock clips for external connections. It'd work fine with a dry cell as filament source and a B battery of 45 or 67 Volts.

You aren't providing enough info for long distance troubleshooting. Are you sure the pass transister is OK or not being current limited? What are you using to measure the voltages? I ask because the 723 is known to oscillate. If you are only using a VOM or DMM, try looking with an oscilloscope also. BTW, isn't Vref supposed to be 7 volts?

Renee---

> Can someone please email me a description of how to build an end fed
> zep?

It's actually pretty simple. You will need either a balun or an antenna tuner---I would recommend the antenna tuner. Taking into account velocity factor, cut a 1/4-wave length of twin-lead transmission line. 300 ohm TV twinlead should work. At the top of your mast, connect one of the two leads to a 1/2-wave length of wire. The other end is left to float.

The 1990 ARRL antenna book has a discussion on end-fed zepps, describing how this works. It seems counterintuitive until you see the current/voltage distributions and how they fold over in the transmission line.

Also, the name ``end-fed zepp'' has come to refer to any antenna of this construction type, not just the tuned type. The HF antenna that I will be putting up will be running through a tuner, have about 15' or so of twinlead, and be attached to a 200' or so radiating element. At an average height of 30' or so, my friend N4AR tells me that this type of setup should let me work the local nets with no problems. It'll have gain, but I haven't asked him about the directivity or DX possibilities.

Hope it helps,

Henry C. Gernhardt, III

> for an antenna. Does anyone have a good idea for some sort of wire
> antenna that can be strung between 2 chimneys that are approx 75 - 90
> feet apart?

If you have the right supports, the right insulators, and the right strain relief, then there shouldn't be a problem stringing a 20M dipole between the chimneys you describe. At my field day site, I saw a full-length (200-odd foot) dipole stretched between two trees, with no center support.

Your only problem would be the coax run. For what I understand to be best results, you need to let the transmission line drop normal to the antenna wire for a ways. You could let the line run over the roofline and down the side of the building, if that is an option.

Otherwise, if you're looking at a wire antenna, consider the end-fed zepp, as your previous post indicated. Simple to build, simple to install, feedpoint at one of the two chimneys rather than offset or in the middle.

Next question: Can you install a chimney mast? at 20M, a shortened yagi, or even a cubical quad, could be feasable.

Good luck,

Henry C. Gernhardt, III

==========
A cheap local repeater could be made with a single low power trx and a
"parrot repeater box".

The parrot repeater operates on a single freq. When someone accesses the
"repeater" his/her speech is stored in a ISD1020AP or 1016AP chip and
subsequently replayed. The only disadvantage is that the caller hears
his/her msg again and the receiver will have to wait for the parrot's
response.
The parrot box was described in a QST article a few years ago.
Suggest you check the QST index at the ARRL site.

Go here and look around for some very good info on repeaters.

http://www.repeater-builder.com/rbtip/

A good antenna and feedline can eat up most of the money. First you have to have a place to put one. Sometimes you can talk the town or county into using some space on one of their buildings or towers or water towers. Cehck with their emergency management people . Have somekind of club plan for emergency communications plan if you do this. If you can do the electronic work yourself you can put one together for around $ 500 for uhf. That is about $ 200 or $ 300 for the controller and about that much for a transceiver that you cna use such as a GE Mastrll an dduplexer and the crystals. If you can get out for under $ 1000 you are doing good.

They can be put together for lots less but you have to know where to shop and how to cut the corners.

The heart of any good repeater is the duplexer and antenna system. If intermod is a problem, you will need preselector filters and even dual isolators if you are sharing a mountain top site with commercial users. The duplexer is not an area to skimp on. Fortunately, you can often find good used ones on the swap group or eBay.

Regards

Pete

==========

It is possible to set up a simple repeater system using two radios and separate antennas. You would need some sort of cw id'r and a timeout timer which can be built with simple ttl logic.

This approach may suffer from overload, where the Tx gets into the Rx antenna, but if you separate the antennas physically it can work well enough.

Using the SAME radio for both Tx and Rx is usually not feasable due to the way the radios work internally.

So separate radios have the best chance of being used as a repeater.

==========

Duplexers can be expensive but they do allow using a single antenna for both Tx and Rx and they also protect the Rx from signal overload.

And, yes, there are many better and more powerful control systems that can be used....

For that matter, you could rig just about any PC to function as a cw ID'r and timeout timer. You could even make it a voice ID using the sound card.

For FCC purposes, you need a control system of some sort, and having the repeater at your house would probably qualify since it would be under direct control.

If you wanted to get fancy, you could rig the PC to be able to respond to a dialup modem and control the repeater that way from a distance.

I imagine there are programs that can be found on the web for controlling a repeater. If not, it'd be fairly simple to create one with enough functionality. This PC controller approach is more then you need for a minimum repeater system, but worth thinking about as a fairly quick way to add a LOT of functionality to the system.

By the way, if you get an Rx that has the CTSS tone decoder option, you could set that up and it would give your repeater a PL access control which most repeaters seem to have these days.

==========

So, you could start with separate antennas and just a few parts for the control system and make it more complex as time goes by. However, at the minimum you will need two radios.

Or at least a separate Rx of some sort.

4343. What Does the SWR Meter Do?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-21 15:51:38 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9jc8gb$7ve$1@uranium.btinternet.com>
Source record: 51440

WHAT THE HANDBOOKS DARE NOT PRINT

The SWR-meter is located in the transmission system immediately at the output of the transmitter. It is often housed in the transmitter case itself.

Immediately following the meter is a variable impedance transforming network, sometimes known as the tuner. The SWR meter can also be housed in the tuner case. But in any event the transmitter and tuner are electrically near to each other with the SWR meter in between.

A transmission line of coaxial or balanced-pair construction runs between the tuner output and the antenna feedpoint.

From one frequency band to another, from one end of a band to the other, the antenna input impedance changes greatly from one complex value to another. These swings in impedance vs frequency are reflected back to the transmitter end of the line unchanged in magnitude.

Transmitters are designed to work into a particular value of load resistance Ro. This is the resistive load into which the transmitter is capable of developing its maximum, undistorted peak output power without exceeding any internal voltage, current or dissipation ratings. It is highly desrable, therefore, for the load on the transmitter to be set to the design value at the start of a transmission and continuously monitored during normal operation.

The tuner's purpose is to transform the wide range of impedances vs frequency, seen looking into the transmission line, to the constant resistive value of Ro at the the tuner input. In modern equipment this operation may be performed automatically, the tuner coils and capacitors being switched by relays or driven by electric motors.

The SWR meter is essentially a 4-arm, RF resistance bridge. Three of the bridge arms are intgral to the meter and the 4th arm, the only variable arm, is the input impedance of the tuner. The circuit is arranged such that the transmitter is the signal source. The values of the bridge ratio arms are chosen such that the 4th arm, the input impedance of the tuner, is effectively the transmitter load.

Inside the meter the bridge RF unbalance voltage is rectified and displayed on a moving coil meter. When the input resistance of the tuner is equal to Ro the bridge is balanced, meter deflection is zero and the transmitter is operating with its design value of load

resistance. The purpose of the SWR meter, therefore, is to indicate that this important condition has been, or has not been realised.

It should be noted that when the bridge is not at balance the meter deflection gives very little information about what the actual load on the transmitter is. There is a very large number of combinations of resistance and reactance which will give a particular off-zero meter deflection and this is further confused by the uncertainty in transmitter RF output volts.

So the meter indicates only whether or not the transmitter load is Ro. But this is all that's required of it. Brightness of a pea lamp would provide the same information more economically if the meter movement and scales were not needed for other transmitter monitoring purposes.

It is now clear that an automatic tuner makes use of the magnitude and phase of the bridge unbalance voltage to maintain the bridge in a state of balance.

Also note, for the meter to indicate correctly, it must be designed around the same value of Ro as the transmitter it is used with. The standard adopted to allow meter interchngeability is Ro = 50 + j0 ohms. So meters generally differ from each other only by their through-power handling capability and operating frequency range. Internal circuitry and physical construction vary widely with frequency range but the basic mode of operation is always that of an RF resistance bridge. It doesn't actually measure anything.

==========
Suggest you have look at the following :

QST , January 2001 , page 65 Hints & Kinks : PSK31/Packet Switchbox, by
KN6TC
This design does not use galvanic isolation between soundcard and radio .

An example of isolation by means of audio transformers can be found in :
QST , June 2001 ,pages 70-71 Hints & Kinks : A Radio/Data interface
connection, by N8ME.

Personally I would always go for an interface with galvanic isolation
between the PC's soundcard and radio, either by means of transformers or
opto-couplers.

Agreed. The meters I have seen run off of rectified, filtered DC.
Therefore the rf frequency characteristic of the meters in all the SWR
bridges I have seen is a "don't care". No problem.....

The only problem that I have run into with QRP stuff is that the
detected reflected voltage can be not much bigger than the voltage drop
in the diode, which can cause a poor match to look good. That is why I
use resistive bridge SWR meters. Resistive bridges are great for QRP,
not so good for QRO.

Nice discussion on how a SWR bridge works though.

Chimneys are a highly visible and attractive "mount" for mast and antenna.
TV and small VHU/UHF arrays can usually be handled.

BUT,

Chimneys are not designed to handle other than simple downward compression
loads. Bending loads and torsion/shearing loads cannot be tolerated very
well without disasterous results.

I would strongly urge you to reconsider attaching anything other than a
small TV or VHF antenna to a chimney. A 20-meter array would easily destroy
the chimney in even a fairly moderate wind.

Go here and look around for some very good info on repeaters.

http://www.repeater-builder.com/rbtip/

A good antenna and feedline can eat up most of the money. First you have to have a place to put one. Sometimes you can talk the town or county into using some space on one of their buildings or towers or water towers. Cehck with their emergency management people . Have somekind of club plan for emergency communications plan if you do this.

4361. New Packet Modem for LAN's

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-22 10:24:27 UTC
From: c.moss_stopspam@blueyonder.co.uk
Message-ID: <6eallt4eck0a5eklvte6dpfjimpnud3e2p@4ax.com>
Source record: 51307

Hi.

I'm trying to find a network chip (as used on Network cards - NICS) that can be easily interfaced to fast 8-bit uP.

It's for a new high-speed (well 128KBit/s min) packet modem that needs to be connected to the pc via LAN and not the usual RS232 port so i need to interface the 8-bit uP to the LAN.

There are various network chips out there (ie, DP8390) but they need something more than a simple 8-bit bus connection and didunt want to have to add extra hardware to deal with it - which would make the modem more expensive :(

Any ideas ?

Regards ... Clive

here are some links,

http://www.ezlink.com/~crash/parks/1distget.html

http://www.lindsaybks.com/

The lindsays book site has many old book reprints with schematics
and info, only problem you will have is getting some of the parts
but they are all available if you look hard enough.

Use a good search engine like Google and search for one tube
radio, or regenerative recievers, may also search grid leak
detectors.

You might want to use an old penny -- they don't make 'em like they used to. From 1864 to 1962, pennies were bronze (95% Cu, 5% Sn and Zn). From 1962 to 1982, brass (95% Cu, 5% Zn). Since 1982, pennies have been only 2.5% copper, the rest zinc. The copper is plated on the outside, so it should work ok as long as all the copper isn't corroded away. But who knows, maybe Zinc Oxide rectifies too.

Although many distributors will sell you single chips, it's less expensive to order small quantities directly from the Analog Devices web site (http://www.analog.com). A single AD9851BRS costs $22.40 there. However, most of their parts, including the AD9851, are shipped from Taiwan, so it takes at least a week to get them.

If you're in more of a hurry, you could try a distributor; the Analog Devices web site has a list of them. I checked a bit, and found one that claims to have stock and will sell single parts - Future Electronics (http://www.futureelectronics.com). But they want $45.58 for a single AD9851. The other ones I checked either don't sell single parts or don't have them in stock.

You could just make one out of a handful of conventional HV diodes.

> are there any compact units ?

Compactness might be a problem, but you could pot the result in epoxy
to squeeze it smaller. Build it and try it out, if is dies in a puff of
smoke you've only lost a few cents of diodes and some time.

Hello,

I just found 3 pcs of the GEC valve TT22. This is a very close
equivalent to KT 88, but a special version with a top cap for the
anode. A max anodevoltage of 1250V and a dissipation of 45W (KT 88 is
42W). The heater is 12.6V 0.8A.
This is a rather scarce valve and usually very expensive. I want
$ 50.- each or best offer. E-mail me if interested.

Best regards,

Arnold Goks�yr

Beware of Analog's shipping and handling charges; they're out of
control. I ordered a half-dozen each AD603s and AD8307s from their site
a few weeks ago, and the S/H for UPS Ground delivery was almost $25.

You might want to use an old penny -- they don't make 'em like they used to. From 1864 to 1962, pennies were bronze (95% Cu, 5% Sn and Zn). From 1962 to 1982, brass (95% Cu, 5% Zn). Since 1982, pennies have been only 2.5% copper, the rest zinc. The copper is plated on the outside, so it should work ok as long as all the copper isn't corroded away. But who knows, maybe Zinc Oxide rectifies too.

Roy Lewallen, W7EL

http://www.usmint.gov/about_the_mint/fun_facts/index.cfm?action=fun_facts2

~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Before silicon rectifiers came along they were made from selenium, and before that from copper/copper oxide. So a penny should work.
Leon
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
I have heard the story of the copper oxide and copper diode, also have heard of using a bowl of lemon juice with a cats whisker as a detector, heard the US Navy used this in the early days.

I myself have used flame rectification by heating a 3/16 diameter rod in a flame to detect with, got poor results but it did work.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Believe it or not, the boyscout handbook still has a xtal radio design using, I think, a safety pin and some raw germanium and/or equivalent detector piece etc..

I also have heard about using a rusty razor blade.

PBS had a special about POWs. One of the things that was talked about revolved around the POWs using all sorts of stuff to make simple rcvrs to keep up on the outside world.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

Sorry, cannot remember the specifics of the show.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
The razor blade part works. When I was 11 I built a crystal radio
with a razor blade, crystal earphone, a disk capacitor (around 200 pF)
and a coil of enameled wire which I tuned with a slider. The razor
blade used a stub of pencil and a paper clip to turn in to a detector.
It worked, but frankly a good point contact germanium diode would
outperform it.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
The copper penny story is almost certainly true. I used to make some very
respectable detectors when I was a kid by taking two pieces of copper bell
wire and roasting one in a gas pilot light until it turned black. I then
twisted
it until the outer black stuff fell off leaving a reddish oxide. I then took
the other wire and scraped it clean and twisted the two together. It worked
as
good as a regular crystal diode for me. I tried a lot of other stuff but
this was
the easiest and always worked and didn't need adjustment.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Posts to rec.antiques.radio+phono:
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
There's the story about a group of WW2 Allied POWs who built a crystal
receiver using a double edge razor blade (Gillete Blue Blade) and the
graphite material from a wood pencil for the detector.They disassembled the
headphones from an Italian Tank commander's helmet that they had stolen,
saving one phone intact and using the other to both wind their coil and for
an antenna. It apparently worked well enough for them to receive BBC
broadcasts
and publish a "Camp Newsletter" on the backs of toilet paper, cigarette
packages and gum wrappers.
Gene
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Go to your local library or book dealer and get a copy of "Voice of the
Crystal." The book describes making a crystal radio entirely with household
materials - even the headphone and tuning capacitor. Several different
designs are presented.
Doug Moore
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
JUST USE ANY CRYSTAL SET CIRCUIT, SUBSTITUTE A SAFETY PIN FOR THE CAT
WHISKER AND A GILLETTE BLUE BLADE FOR THE GALENA. THATS ALL THERE IS TO
IT.
Bill Turner WA0ABI
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
Bruce:
I've written a book on precisely this subject. I invite you to take a look
here:

http://www.mindspring.com/~pfriedr/

To all the members of the group...let me know what you think.

Pete
(I have a copy coming from Lindsay)
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
emailed responses:
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
I believe that gun bluing is indeed the same chemical, but I've never tried the appropriate experiment. I look forward to reading your summary.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
IIRC, the razor blade had to be a "blue blade". The bluing process deposits a layer of a selenium compound, and there's half of your diode!
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
You're welcome. The guy was working on making his own transistors, but didn't have a way to evaluate his experiments. I sent him an early Tektronix curve
tracer to help him out. I understand now he is experimenting with making his own vacuum tubes. The guy is really clever, and a heck of a good writer. I found the book fascinating even if I didn't intend to try constructing the stuff. His use of the piezo element out of a cigarette lighter for the headphone was really ingenious.

Years ago, I experimented with different substances for detectors, and had some luck with copper oxide. Never tried the razor blade, but I've heard it works too. My grandfather gave me a large Galena crystal once, and it was enough for a hundred detectors. It's a shame things have gotten so complex these days.

By the way, I'm quite into the old ways, running an all vacuum-tube Amateur Radio HF station. I do have a modern handi talkie, and a modern 10m transceiver in the car, but love the old gear because you have to constantly keep an eye on it, tune it for optimum and such. Oh the joys of adjusting a Pi Network. It's kind of like running a steam locomotive - make a mistake and BOOM!

Interesting! Everyone has their pet antenna, some having "magical" claims. I much prefer the vertical 1/4-wave mounted at ground level and using bits of TV coax as ground radials. Single pole-in-the-ground mount, old 27MHz CB antenna modified, impedance 50-Ohms (as opposed to 75 with the dipole), does not suffer from ground reflections modifying impedance, omni-directional, low profile, mechanically sound and easy to erect. Put a flag on it and no-one know you have an antenna!

To get a horisontal 1/2-wave to perform the same you need it 0.6-wl over the gound, and even then you cannot communicate along the axis of the antenna!

Sorry, I missed the point. Are you trying to sell something? If so then what is it? Everythin that you stated was a rather basic description of how to measure VSWR. Note the inclusion of the V. It is the Voltage Standing Wave Ratio that is measured. All VSWR measure the voltage relationship, not power. If this were not so then meter calibration would be very much different.

Yeah: consider another project. This part is unavailable. It's
long out of production, so there are no NOS stocks available.
It never really made it to the surplus market, so there are no
surplus parts available either.

There are other modem chips available (e.g. MX614), but
they are not drop-in replacements.

4383. FT: Computer gear for HF Rig

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-23 16:19:48 UTC
From: rkasprow@hotmail.com
Message-ID: <d8f49a6c.0107230819.413fba42@posting.google.com>
Source record: 51330

I have the following gear available for trade / sale on a "newer" HF
rig, specifically interested
in the following:

* Kenwood TS-50
* Yeasu FT-100
* ICOM IC-706
* Alinco DX-70 / DX-77
* or other smaller case HF mobile

What I've got.

// Compaq Deskpro Server
400 MHZ, 128 MB Ram, CD-ROM, 8GB HD, 10/100 NIC, AGP Video, Mouse +
Keyboard,
Windows 2000 Professional.
More ram is available.

// Compaq Deskpro Desktop
350MHZ, 128 MB Ram, CD-ROM, 5 GB SCSI-2 HD, 10/100 NIC, Adaptec Ultra
Wide SCSI Card,
AGP Video, Mouse + Keyboard, Windows 2000 Professional.
More ram is available.

// Compaq Deskpro Desktop
350MHZ, 128 MB Ram, CD-ROM, 6 GB HD, 10/100 NIC, AGP Video, Mouse +
Keyboard,
Windows 2000 Professional.
More ram is available.

// Compaq Deskpro Desktop - Small Form Factor
466MHZ, 128 MB Ram, 8 GB HD, 10/100 NIC, AGP Video, Mouse + Keyboard,
Windows 2000 Professional.
More ram is available.

// Sun SparcSERVER 10
50-MHZ RISC processor, 96 MB Ram, 4 GB Hard SCSI Drive, CG 6 Color
frame buffer,
On-board fast SCSI controller, On-board 10-100 base T Ethernet,
On-board sound,
additional fast SCSI controller, additional 10-100 base T Ethernet
controller, Mouse + Keyboard.
Excellent webserver, file server and strong Unix operating system.

// Sun SparcSTATION 5
70-MHZ RISC processor, 64 MB Ram, 2 GB Hard SCSI Drive, CG 6 Color
frame buffer,

On-board fast SCSI controller, On-board 10-100 base T Ethernet,
On-board Sound,
additional fast SCSI controller, additional 10-100 base T Ethernet
controller, Mouse + Keyboard.
Excellent webserver, file server and strong Unix operating system.

// Hewlett Packard Rack Mount Network Hubs
4 available, 2 14 port and 2 15 port hubs. All are in excellent
condition and recently removed
from service. These are rack mount servers.

// Proxima LightBook LB20 DeskTop Projector
SVGA and RCA inputs, 200 ANSI lumens, Serial jack, Computer in jack,
Monitor out jack, Video in jack,
Audio in & out, TV output, Twin Lamp, True SVGA compatibility (800 x
600), International power supply,
LightBoard drawing tool, Remote control, Lightweight (11 pounds - 13.5
x 9.25 x 5 inches),
Custom padded case.

This unit is in excellent condition and includes all
the original equipment (cables + books).

If you see something you like, please let me know. I am open to trades
or sales on any of the
machines. Willing to trade multiple machines for the right gear. Sales
always welcome ...

Thank you!

4384. Re: What Does the SWR Meter Do?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-23 16:47:54 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9jhkht$697$1@uranium.btinternet.com>
Source record: 51331

The only place I mentioned SWR is in the incorrect name of the meter. Its purpose can be fully and very simply explained without a mention of SWR. The abused thing has nothing to do with SWR. Although it doesn't measure anything it is, nevertheless, a very important instrument.

The transmission line and SWR associated with the meter exist only in the guru's and John's imagination.
--
PS. You can't have a VoltageSWR without a CurrentSWR. Did you know they both have the same magnitude? So SWR all by itself is a quite adequate description. There's no need to distinguish one from the other. But why do you persist in bringing SWR back into the discussion?

4385. Tuners, Couplers, Hamsticks, and other things

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-23 17:14:12 UTC
From: Jerry Oxendine <joxendi@bellsouth.net>
Message-ID: <XQY67.4219$UB6.349114@e3500-atl1.usenetserver.com>
Source record: 51332

I was away all last week at a continuing edu. activity. During this school, I
had a few conversations with a "bigwig" electronics type who advises the *OTHER* bigwigs on communications matters. Seems this man and his USAF counterpart favor using SGC couplers/whip combos on all corporate vehicles for HF as opposed to resonant antennas. For example, he called the Screwdriver antennas "garage" technology. To which, I called tuners "voodoo" technology and argued that most of the good ideas of the past century came from garages--Henry Ford's car, the airplane, and Microsoft Windows to name a few.

I was taught, thru study and 30 years experience, that nothing beats a resonant
antenna. No, I don't have an electronics/engineering degree. I was taught by
hams and books, AND mistakes what works and what doesn't. I can't explain the microscopic reasons why something works, but I *can* do fairly detailed experiments, etc. I know somewhat more than the "basics".

The powers that be in this organization want to equip the vehicles with couplers/tuners/whips to provide touch-of-a-button access to multiple HF bands. I have been saying from the field, "NO, you don't want to do that IF you want maximum performance, flexibility, and cost effectiveness". The couplers cost lotsa $$$$$. The SD's cost almost half that even if you equip the vehicles with permanently installed analyzers or SAMs. Seems to me that the degreed types lose touch with reality and believe that any problem can be
solved by throwing money at it. Typical of government, too! To them, a device must have a "Big Name" on it to be good. IF it said Rockwell Collins on it, they'd be knocking on their doors.

Final qualifier. Yes, I build screwdrivers-good ones, too. But I have bowed
out of the bid/sales thing because I am also a member of the group. Conflict of interest, etc. But I DO believe the SD to be the way to go--especially if you
are able to get a good price ($200 or less). I think the SD is the way for the
org. to go for mobile comms.

SO!! Am I wrong? Do you think a coupler/whip will "beat" a screwdriver in a "shootout"? Especially if the SD has a 2-3" coil at 8 TPI of #14 wire? If it's
ok, I'd like to forward your comments to my friend and see what he thinks. Incidentally, I loaned one of my SD's to the man to test and compare. When

it
comes to buying them on a national level, he'll have to look elsewhere.
Which
one, do you think, will win based on its merits.

Bob,

Sounds just like me and *most* other hams around! I did the same thing,
especially back when I had tube rigs. Handy if I happened to burn up my
filaments. After I retired my last tube rig, the tubes accumulated
until-----well,
you know. So, I started taking them to hamfests and selling them for what I
could get. That's basically about the only way I could get shed of them.
Good
luck with your "collection".

There used to be a program for decoding MDT from a scanner with source code. It had all the windows API calls and set up multiple buffers for the sound data, then called a DLL written in C for the DSP part. I think it was called MDTwin.

You might also search for PSK31 source codes. I've seen a few windows programs with source as well.

4388. Re: Tuners, Couplers, Hamsticks, and other things

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-23 18:20:17 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3B5C6AE1.AE62EDEE@eznec.com>
Source record: 51335

I seriously doubt that the SGC/whip combo would beat a well designed screwdriver in a shootout. But the objective of these people isn't to win a shootout -- it's to reliably communicate under all possible conditions. And that's a very different objective. Having a full battery of environmental tests run on your product -- heat, cold, moisture, salt spray, vibration and so forth -- would be the first step in convincing your potential customers that they can count on your antenna when the chips are down. Next would be to install your antennas on a few hundred vehicles that operate at all times of day and night all over the world on a variety of frequencies. After these have been in operation long enough to show that your antenna has a very low failure rate in actual operation when subjected to smog, sand, dirt, and temperature extremes, your potential customers will probably listen. Now, I'll bet you're thinking, that would be awfully expensive, and I'd have to charge a whole lot more for it. And now you're beginning to realize why the unit they do buy is so expensive.

Amateurs who aren't also professional engineers or who work in electronic product development seldom understand the vast difference between building up one or a couple of dozen prototypes, and making a product that will reliably work day in and day out, and can be built repeatably by the thousands. I worked for Tektronix for years. Their development cycle is probably typical of quality electronic equipment manufacturers. It might be a couple of years between the time a prototype is working and the product is ready for sale. A typical product development cycle would involve building a hundred or so complete instruments, subjecting them to elevated temperature testing to accelerate failures, running them through extensive environmental, mechanical, EMI, and performance testing. When all the bugs seemed to be fixed, another hundred or so were built and the whole process repeated. Only after this second process was successfully completed were the instruments offered for sale. The first units produced often got special testing and attention to further identify problems, and were sometimes used only for demos. Often a military contract would require additional reliability and environmental testing. Do you have any idea what all that testing costs? A person building scopes in his garage could produce an instrument for a fraction of the price -- but with the Tek instrument you are getting what you're paying for.

And that's the difference between "garage technology" and a "big name" product.

Indeed. I got burnt on this - badly - last year. All I
wanted was two AD8307s, but when all was said and done the
shipping (to Canada) was going to be three times the cost
of the parts. Worse, the parcel delivery took longer
than plain old snail mail would have taken.

I refused the UPS parcel and eventually got a refund. This
took a while.

A shame: it could be a really handy service.

Hi, Everybody,

I asked this question a long time ago, and the few answers I got seemed really unsatisfactory, probably due to my inability to set up the scenario. I'd like to pose it again:

Pretend you have two absolutely identical crystal filters. They have the same -6 dB bandwidth, insertion loss, ultimate rejection, and shape factor.

You cascade them in an IF strip. They are both terminated properly and well-isolated with a suitable amplifier between them.

Isn't it true that the equivalent BW of the system will be somewhat narrower than either of the original filters? For example, won't the -3 dB points of a single filter become the new -6 dB points of the cascaded pair?

Regards,

Al W6LX

If this is a highest priority project, you might try salvaging old telecom equipment. I built my packet modem out of a chip from an old 1200 bd modem, they used to be in very old faxes too. BEWARE: This chip is a piece of s...
It's just the really basic, a properly programmed PIC could do the same job better, if it's for packet itself consider a TNC. I don't know how in Canada, but they appear here from time to time on the Flea Market section of our PR boards ...

Yes, the -6 dB points of the pair will be the -3 dB points of a single filter, and the combination will always be narrower than a single filter. If the filters have very steep skirts (typical of crystal filters), the bandwidth difference will be small; if the skirts aren't so steep, the difference will be greater.

I have an over-simple judgment on this question :

- if the two filters are absolutely identical,
- if they have the same - 3 dB AND - 6dB bandwidth, same shape factor,
- if they are properly terminated,
- if they are well isolated, with a suitable buffer and without any coupling between them,

..... and if you tune a RF generator on the - 3dB frequency (for the first filter), then the total attenuation will be 3 + 3 = 6 dB
All the points of the resulting attenuation curve will be the result of the sum of the attenuation of each filter, or twice the attenuation of a single filter. The -3 dB points of a single filter will become the -6 dB points of the cascaded pair. The resulting BW will be narrower.

It's for me elementary algebra !

But perhaps on my side, there is something else, something wrong or I don't understand something important !

Thank you for your comments,

Hassu,
I did a search on MDTwin, but I didn't get any meaningful returns. What is "MDT" anyway??

I already looked at a couple of PSK 31 open-sources. Most of them take a monaural input, process the PSK, and output text to the computer display. Although useful for academic purposes, they really wouldn't save much work, as one still has to figure out how to decompose the soundcard buffer output into left and right channel information (I and Q), and then figure out how to put this back out as sound while duplexing input and output in a continuous stream.

I did find some useful work by a Brit who has published several examples of duplex input/output using DirectX calls from Visual Basic. His work was for monaural sound....I'm trying to figure how to separate the left and right input components.

The quest continues.

Thanks,
Joe

4396. using Tektronix plug-ins as stand-alones?

Newsgroup: rec.radio.amateur.homebrew

I have been offered a Tektronix 1L20 spectrum analyzer plug-in module. It was designed to be used with the Tek 500 series oscilloscopes. I have an HP oscilloscope however. I am assuming that the only other requirement for this plug-in would be to provide it with the right power sources??

Has anyone out there had experience trying to make-do with plug-ins as effectively stand-alone instruments? Any comments would be appreciated.

I bought at last Saturday's Pomona swap meet a very nice commercial or military 2x MRF422 power amplifier board. It is very similar (identical?) to the Motorola EB27A as far as the RF design is concerned, but the bias supply is completely different. Each transistor base is fed from a 4 terminal device that looks like an flange mounted RF transistor, but is not..

The markings are:

ACR
Z0-28F (could be a zero or an o)
1363W

From the top, clockwise, term 1 goes to the supply (presumably28V?)
term 2 is the Output,
3 is fed through a 100 ohm and 1000 ohm variable R in series from the +ve supply
4 is ground.
Liberal chip capacitor bypassing.

Has anyone come across these devices before?

I would like to use this PA with a qrp radio but would like to get some information on these devices before I fire it up :-)

Or has anyone any idea who made this board and what it came from? The quality is good enough to be from Collins or similar. It has relay switched 1/2, 1, 2, and 6 dB attenuators on the front end and a LPF on the output, input and output RF measurement transformers and very nice plastic encapsulated broadband rf transformers, D-sub combo connectors for everything.... Sound familiar to anyone?

Next stop the smoke test I suppose :-)

You may find it easier and less of a headache just to locate a used 5000 series mainframe on the internet. If nothing else, check out ebay - there are usually several there for sale at a time.

On the other hand, sounds like a fun thing to try if you've nothing else to do...

Hi, Reg & all -

Actually, there is a wide variety of SWR meter circuits, some of which don't involve bridge balancing. Some of which have separate forward and reverse selections versus those with only a self-correcting forward range. And for any reasonably designed unit, if the calibrate / reverse adjust is set, the forward indication *is* a display of SWR.

After all, there *is* a connection from the meter to the tuner. It may be short in physical length, but it's there (the transmit capability really suffers otherwise). And, as you say, the standard impedance design value is 50 ohms resistive. So that's what the meter is reading.

So:
1) What's the complaint? The indication *is* of a real, measured, quantifiable value (as real as volts, amps, watts, or hours spent on Usenet).
2) Even a mismatch magnitude detector still gives you something to tune with. Is that bad?
3) Even phase/magnitude detectors can give automatic tuner units (ATUs) fits - optimizing the tuning is handled by many by just trying all the possibilities and using the best one. Try doing a stability state analysis of them and you'll see why many designers throw up their hands and use such crude methods.
4) SWR has often been given too much emphasis - a lossy antenna can have its SWR lowered giving it the appearance of higher performance that it really has. But that doesn't mean it is meaningless. The amount of mismatch is as important as its presence or absence.

Best to you and 73-

Jim Horn, WB9SYN/6

another device to use is AM7910 or 7911, believe they weren't too
difficult to trace, also used TCM3101 - it worked provided you didn't
connect any outer resistors as mentioned in the manual, TCM3101 was a
ceramic device, I use it in some of my TNC's, cannot tell which is the
best, perhaps it is some other close data devices like TCM3102 or
TCM3104?
We didin't want to pay so we used whatever was offered from friends in
the industry, hi. Also made some experiments with AM7911 on a board,
and AM7910 was used in my first KPC-2, worked ufb on 20m provided an
x-y scope was used to tune the frequency and still very critical to
tune the FT-7 or Drake R-4C, believe it was narrower than TCM3105, but
it worked always ufb on 2m

not much to add to what Roy says, but one reason for using filters at
two stages is to improve ultimate rejection outside the passband. It
might sometimes be difficult because of spurious leaks, but again, Roy
can explain this better than I

IF
>you want maximum performance, flexibility, and cost effectiveness".

Having some experience with the US Gummint communications field, I can tell you that touch-of-a-button access to multiple bands is the key to success if you are expecting the operator to be anything but a guy with a lot of radio training. The people that use them just NEED TO COMMUNICATE RELIABLY - they don't wanna screw around with JS antennas, they don't care about getting a 5X9 report, they don't care about audio quality, and they sure as hell don't want to deal with something that's gonna bust on them when they're out in the boonies.

Believe it or not, radios are just appliances and/or tools to them. Just a means to an end of getting a message from point A to point B - reliably. If it costs 'em an extra grand, it is WELL worth it.

Lord only knows how many final tubes and transistors have been fried by untrained operators prior to the introduction of automatic antenna tuners. "Geez, I can never remember - is it DIP THE GRID AND PEAK THE PLATE or DIP THE PLATE AND PEAK THE GRID??"

As I used to point out to my radar classes at Texas Instruments, the only reason we use VSWR instead of ISWR is that we can call it "viz-wahr" which sounds much cooler than "iz-wahr." They have the same values, mean the same thing and can be used interchangeably. The only difference is in how they are measured, and for whatever reasons, historical and otherwise, it has turned out that voltage measurements seem to be preferred to current measurements.

Personally, I liked Reg's posting very much. It reminded me of why, when I tune my MFJ 989C tuner, I never look at anything except the "Reflected Power" meter reading.

A 5K mainframe will only set the respondent back $30 or $40! They are incredibly inexpensive if you need a low response, low noise scope (I have 3).

I have a 5L4 spectrum analyzer -- if you have the manual you could use it without a 5k mainframe, but time=money. The 5L4 is beautifully built with very nice filters etc., but I think that you can effect much of the same analysis with a decent sound card these days.

4408. MC13142 Projects and Plans?

Source record: 51353

I've been staring at the nearly all-in-one broadband rcvr frontend from Motorola on-a-chip, the MC13142. I'm not a hardware engineer but my extra class studies tempt me to play with this.

Has anyone published some plans using this chip for experimenters in upper UHF? Some of the units apparently go up to 2.4 GHz (even though only 1.8MHz is advertised). So with luck I could get a cheap way to AO-40? And with its built-in LNA, VCO, Mixer, etc. it starts to look like a universal transverter. Just find low parasitic reactance ways to swap out filters and tuning elements.

Am I on the right track here? Is there anything better to do simple microwave experiments?

I had a similar problem, except that I was denied permission to erect an antenna on the chimney, or even the balcony! The thoughts were that all radio hams jam all TVs so don't let 'em have anything that could transmit!

I placed a 1/4-wave wooden brush-handle/fibre-glass fishing rod out on the balcony and sure enough I got complaints of interference! "Egg on the face" calmed a lot of people down, then I erected a real antenna:

1. Magnetic loop antenna built using a packing crate. Covered 7MHz - 30MHz and remote tuned using a model servo. The antenna was painted and had a dartboard on it so it was not recognisable as an antenna.

2. Vertical 1/4-wave mounted on the window ledge. A V shaped bit of nylon rope at the top of the window allowed the antenna to lean out at about 25 degrees from vertical. the bottom sat on the window ledge. A loading coil 53 turns, 10cm Dia. allowed a crocodile clip to bring it to resonance on 3.5MHz, 7MHz, 10MHz and 14MHz. Antenna erected in 45 seconds when required and removed just as quick. Even worked Japan on it with only 50 watts! For 10, 12, 15, 17, and 20 the ant would be only 1/2 the length. Ground was a) metal available for the building b) indoor radials.

Don't forget that if you shove up a permanent antenna then everyone will see it. If you have something as described that is temporary, only there when you use it then no-one will notice it. If they do see you using it over the weekend then any complaint will only reveal the antenna has gone by Monday morning!

There you have it by general concensus; assuming the filters are exactly identical then the -3dB point will become a -6dB point. But:

No-one has yet mentioned other factors, such as the in-band ripple will also double in depth. This could be particularly objectionable when receiving weak signals. If the two filters were deliberately loaded slightly differently then the ripples could be shifted a little to give an improvement instead of degredation.

Insertion loss will double since the filters are passive and have an insertion loss; typically 3dB.

Filters also tend to "ring" a bit. This effect is not noticeable with wide bandwidth filters, but with narrow BW filters (CW etc.) the effect is quite noticeable. If you have two such filters cascaded then the effect will be ringing upon ringing.

The easiest way to find out is to try it. If it works Ok for you then use it. If Hammcom stops decoding then take it out.

4417. Frequency Selection Advice.....

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-24 13:07:30 UTC
From: Paul Breed <Paul@Rasdoc.com>
Message-ID: <36rqlt4bbjosslgep8aqs5v8fdr573qbr4@4ax.com>
Source record: 51362

I am working on a Project to try and set the Solar Powered RC altitude record.

I am am thinking about how to establish the control link reliably to 20 Miles line of sight.

I've had a regulatory setback.... I read part 97.215 to be an exception that allowed you to transmit RC without identification. So I had planned to build a 25 or 100W 6M RC Tx, and to provide CW identification every 10Min thus removing me from the restrictions of 97.215, alas when I asked the FCC/ARRL for clarification they did not agree with that interpitation of the rules.

Thus for any RC application on the Ham bands I am limited to 1W TX output power.

I will be using a 900Mhz or 2.4Ghz ATV transmitter with Telemetry on the Audio channel for downlink, and thus I will have a tracking AZ-EL antenna setup that could also hold a TX antenna with some gain.

My Uplink choices:
1)1 W on 6M using standard 6M RC reciever on the aircraft and a homebrew 1W 6M transmitter on the ground with a small 6M antenna like 2 or 3 el 6M beam.. As per the FCC regs RC is prohibited from transmitting more than 1W on the ham bands.
How well would 1W on 6M do for a 20 mile Line of site path?

2)1W on some other Ham band (70cm for instance) This would require both a homebrew TX and a homebrew RX, but it would allow the use of an antenna with some real Gain. (say a Big 70cm Yagi)
Aux Question: How would one go about building a very small lightweight 70cm Rx? I'm willing and able to do a PCB Design using SMT components.

3)25W on 27.255 Mhz FCC part 95 aloows you to build your own R/C transmitter for operation on 27.255Mhz with a maximum envelope power output of 25W. So this would require a homebrew TX and RX.
(Home brew on 27Mhz is a lot easier than on 70cm)

Additional General Technical notes.
Both the ground station and the Aircraft will have local GPS receivers with 1pps outputs. This would allow a VCXO slaved to the GPS to provide very tight frequency tolerance on both ends.
The aircraft will be quite slow so doppler should not be a problem.

One thought for the Airborne 70cm Homebrew RX would be to use a receiving transverter and a standard 6M RX receiver.
This could allow you to use a normal 6M RC transmitter when the

aircraft is close to the pilot and ground station and to switch to a Higher frequency with more TX Antenna gain as the Aircraft gets farther away.

Any Advice would be welcome.

Paul (Kl7JG)

I would think that 1 watt would be plenty for what you want to do. I have talked with the airplanes on 2 meters at distances of over 100 miles and they were using HTs with 5 watts or less output. Have you ran any pathloss calcuations for the distance ? Remember that is line of sight and not over the earth.

The old engineering rule of swings and roundabouts applies here. In
path engineering, the term "figure of merit" is used.

The free space pathloss between isotropic radiators is:

a = 32.5 + 20logD(km) + 20logF(MHz) (dB)

As you go up in frequency from say 6m to 70cm, 20logF is about 19dB
more, so (ther considerations aside) you need to extract this much
combined EXTRA gain from the pair of antennae on the circuit.
Assuming that weight is an aircraft consideration, gain and/or
steerability are fairly much precluded up there. To get 19dB more
gain at 70cms than at 6m on the graound is some array, and the
beamwidth will make tracking requirements more stringent.

Review your a/c Rx usable sig level and apply the above FSPL calc to
the 20mi path (note the above form is the metric - km - version).
This will indicate the EIRP required on the ground, after
adding/subtracting the deemed a/c gain over isotropic.

>Aux Question: How would one go about building a very small lightweight
>70cm Rx?

Cannibalise a commercial handheld. You should be able to get low
current and good sensitivity from and oldish (non-synthesised) unit.
Stay focussed on your mission rather than distractions like designing

wheels - er, receivers ;-)

>3)25W on 27.255 Mhz FCC part 95 aloows you to build your own R/C
>transmitter for operation on 27.255Mhz with a maximum envelope power

Cannibalism is surely easier. Stick to the mission's core business.

Not necessary if you are using normal xtal reference in half-decent
gear at both ends of the cct.

well that puts you in the middle of the CB stuff and most of the semi's stay at 27.185 but with amp and clipping the audio limiter circut you will have a very big danger from their bleeding into that freq.

not much to add to what Roy says, but one reason for using filters at
two stages is to improve ultimate rejection outside the passband. It
might sometimes be difficult because of spurious leaks, but again, Roy
can explain this better than I

another device to use is AM7910 or 7911, believe they weren't too
difficult to trace, also used TCM3101 - it worked provided you didn't
connect any outer resistors as mentioned in the manual, TCM3101 was a
ceramic device, I use it in some of my TNC's, cannot tell which is the
best, perhaps it is some other close data devices like TCM3102 or
TCM3104?
We didin't want to pay so we used whatever was offered from friends in
the industry, hi. Also made some experiments with AM7911 on a board,
and AM7910 was used in my first KPC-2, worked ufb on 20m provided an
x-y scope was used to tune the frequency and still very critical to
tune the FT-7 or Drake R-4C, believe it was narrower than TCM3105, but
it worked always ufb on 2m

Source record: 51371

The swr meter in a transmitter is to aid in making sure that it is transmitting into a load it can handle. It is not a lab instrument. It does not tell if the impedance is higher or lower than the design impedance, only that it is not the same. To have any real meaning other than this , the swr meter will have to be moved to the load end of the line. Then it will still only indicate if the load is not the same as the design impedance.
The people here are trying to make a big deal out of a simple and really dumb instrument.

French au bas :

Hi, I'll explain you my problem. My city's police department crypts now her radio communications with a speech inverter system. For example, all sounds over than 1700Hz are reflexted under this sound frequency and opposite for the sounds under this frequency. I want make a little electronic system to decrypt this transmissions. It's for this reason that I need your help to know what kind of electronic piece I need... Thanks. If you may send me a plan or an exact procedure who to do it. Thanks!

M. Heppell

Please send me your answer to mheppell@sympatico.ca

Bonjour, je vous expose mon probl�me. La police de ma ville crypte maintenant ses communications radio avec un syst�me d'inversion de la voix. C'est � dire que, par exemple, tous les sons plus aigus que 1700Hz sont invers�s vers le dessous de cette fr�quence de son et le contraire pour les sons plus graves. �a donne un genre de charabia au lieu de la parole normale. Je veux d�crypter ou r�inverser pour pouvoir d�chiffrer ces transmissions. C'est l�gal au Canada seulement, il faut trouver comment les d�coder. C'est pourquoi je fais appel � vous pour trouver quel pi�ce �lectronique peut faire ce travail. Comme �a, je pourrais aller l'acheter et la brancher sur mon balayeur d'onde au lieu d'acheter au magasin un appareil qui fait ce travail et qui co�te plus de 150$ (750 francs). Merci d'avance!

M. Heppell

This usually is mainly a function of the phase response of the filter,
among other parameters. And phase response is in turn a function of the
design algorithm for the filter.

Narrow filters need not ring . . . the 50-Hz filter bandwidth on my
IC-756PRO does not ring at all - it just narrows the frequency response.

Stay completely away from any 27 MHz frequency. It is also a good idea to
avoid the usual RC air and ground control frequencies.

Sounds to me like you would be in a good position to obtain a waiver or
special license from the FCC to cover your radio link needs here.

4437. Homebrewing an Antenna analyser

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-25 14:09:24 UTC
From: s@9bit.qc.ca
Message-ID: <3b5ec729.4406344@news.9bit.qc.ca>
Source record: 51384

I've gone through my pile of QSTs from 1987 to 2000 to find an article on homebrewing an antenna analyser with no success. Has MFJ got a Patent on this, so no one can publish, or its just that I'm missing that its a fairly complicated project?

I'm not an electronic technician, but I can understand construction articles. I just can't build from theory. (Darn handbooks and schematics.)

I already homebuilt a RF noise bridge which has been useful.
I already own a PACO grid dip meter.
I already own a frequency counter.

I'm looking for a way to hook up my test equipment in an antenna analyser configuration. I know I can hook up my tranceiver to the antenna to make swr measurements. (its not legal to swoosh the band tho)

Anyway, in the ARRL handbook and on the internet I did a search for a "return loss bridge" and came up with schematics for a 50 ohms unit. (HA8ET homebrew page) I think its the base for an antenna analyser.

Now: Am I right to say that My grid dip is some kind of an RF oscillator calibrated on HF? Can I get somekind of an output from my grid-dip into the return-loss bridge ?

Where should I tap the RF from? Its a tube type unit.
Should I add a tap on the grid ? but I don't know how or if it will generate enough RF energy or if it will detune the unit.

For the meter part, I see everywhere you make measurements with a voltmeter and then look at conversion tables from voltmeter readings to return loss and swr. Can I just simply buy a meter movement with a SWR scale and connect it somehow to read SWR directly ? .
How about a switch to short the bridge and calibrate, then flip the switch to read swr ?

Ok, ok if you tell me to build the return loss bridge first and worry later, its just what I might do ...

George, W5YR wrote
The response function of the pair will be the
product of the response functions of each.
==========

George, I do hope you don't think me a little too nitpicking.

The response function of a network includes the values of its designated terminating impedances Ro. But the input impedance of the second network will inherently differ from Ro and so the response of the first network will change.

Similarly, the source impedance for the second network will inherently differ from Ro and the response of the second network will also change.

So overall response of the cascaded pair of networks may differ significantly from what is expected.

I'm sure you are aware of this but you didn't feel like making a song and dance about it. For amateur purposes and indeed other applications I agree the product of the response functions will be in the right ball park.

Just had a second thought - will the pair of changes tend to cancel each other out?
===

27.255 is cb channel 23. That seems odd because most RC toys operate at
27.045 (or is it 27.145, it's one of those odd skips for class C operation).
I would stay away from the CB band all together. The first guy to key up on
AM with 100+ watts and splattery audio (even 200 KHz away from your freq)
would give you a serious QRM issue.

Just a thought, but what if your experiment were considered a beacon?

Building an analyzer like the MFJ doesn't require any unusual or patented technology, but it's definitely a complicated project. Even a broadband analog bridge like the ones made years ago by GR require a lot of care and knowledge to control the inevitable stray impedances that can reduce the accuracy to the point of uselessness.

I recommend that you take a look at the return loss and resistance bridges in _Solid State Design For the Radio Amateur_ by Doug DeMaw and Wes Hayward, published by the ARRL. I've used variations of the ones in that book for years to measure antenna impedances. They're simple, easy to construct and understand, and are capable of good accuracy when carefully made. They would at least provide an introduction to the issues you've got to deal with when making these sorts of measurements.

No problem, Reg . . .

I failed to elaborate on the structure I had in mind. First I was appealing to the simple-minded notion of cascading LLFPB networks. Second, I thought that the original question involved isolation of the two filters by intervening amplifiers which would assure fixed source and load terminations whether one or two filters was under consideration.

Your point is well taken in that if the termination of the first filter is the input impedance of the second filter, etc. then things are indeed up for discussion.

To me, a "filter" always includes the termination and source impedances. I assumed in the above that these would be fixed.

Your last point is a puzzler for directly cascaded filters: what effect on the second filter does the first filter have acting as a source with it own impedance? And what effect does the second filter have on the first filter acting as its termination impedance? Would they compensate in some karmaic fashion?

Thanks for the note.

> cancel each other out?

And as always the answer is "that depends".

Assuming you keep things simple you have more or less you have two categories of filter. One group like the butterworth is constant impedance in the passband. The other group like the eliptical has a passband impedance that varies. Both types vary impedance as you move out of the passband.

If you cascade two constant impedance filters the passband won't get super weird. If you cascade filters with non-constant impedance you can pretty much be sure that the net ripple will be significantly worse than the product of the responses will predict. Nothing terribly strange here, the constant impedance filters look like 50 ohms in passband and the other's don't. The ones that don't look like 50 ohms affect each other more.

As you go from passband to stop band both types of filter will go through some major changes in impedance. Depending on the prototype they will go from near open to near short or from near short to near open as they do the transition. In either case things will get pretty strange. Normally the filter is trying to reject signals by reflecting them back to the source. When you cascade identical filters the reflection is heading into a more or less matched source (high Z to high Z or low Z to low Z, not a conjugate match) . The net result will be a lump in the transition region because less of the signal is reflected than you would expect. It would be nice if it hit at just the right point to flatten things, but generally it hits at about -6 db or so on the original passband. Again nothing to surprising. Reflection, impedance and passband characteristics are all related to each other.

A simple way to get around all of this if you don't want to use an amplifier is to just put a resistive attenuator between the two filters. It won't help the noise figure, but a 10 db pad in between the two filters will do wonders for keeping the them from messing with each other.

Another thing that can be done is to design an L/C matching network between the filters and at each end. This can improve the net result

from a cascade if the filters are simple enough. The free lunch principle applies though, you will always do better if you design the two filters to be cascaded.

Hope that helps ....

OK, I'll bite: how can a filter *not* ring?

I have a mental model of a filter as one or more "flywheels" or
resonant systems. We have to charge up the flywheels over a number of
revolutions to get signal through, and that is both phase delay and
off-frequency rejection (as off-frequencies sometimes help and
sometimes oppose). It seems to me that, once charged up, a flywheel
must run down (that is, "ring"), although that could happen quickly
with low Q. My model of filtering *is* energy storage.

What is wrong with my picture?

It is relatively easy to do. Simply get an audio mixer hybrid device
(pair of coupled transformers). Feed the scrambled audio into one port,
and a 1700 MHz carrier into the other. Amplify recovered, descrambled
audio at the output port. Many years ago, when these were the cheapest
and simplest scrambling means available, we discovered how easy they
were to defeat, and moved on to more complex analog "rolling-code" type
scramblers. Of course nowdays, most voice encryption is digital, and
difficult to decrypt without a very sophistocated computer. But for
police work, only privacy, not true security is needed, so DES mode
encryption works just fine for 99% of applications.

Hi Terry,

What's missing is that the filter in question is a digital filter rather than an analog filter. That lets you do some things with the delay response that you could not do without a *lot* of effort on an analog filter.

As an analog bandpass filter gets narrower you do get ringing due to a number of causes, one of which is the Q of the components. Another contributor is the tradeoff between a good steep cutoff and an increase in phase error over the passband. If you want to get rid of the effect with analog parts you build a delay equalizer. Think of it as a flywheel that you make run backwards. If the phase response is flat (equal delay) then a pulse will not be stretched extra much by the filter.

With some forms of digital filter you can play with amplitude response and phase response independently of each other. That makes it *much* easier to get things that do not ring a lot.

In either case though you still have the problem that if you hit the filter with a pulse it will block for a period of time that gets longer as the filter gets narrower. Since it only blocks for one cycle it's not technically ringing, but it is a period of time that you don't get a lot of useful stuff out the other end.

Hope this helps ...

OK, here's how you do it.

Take a busted computer power supply, find the coil and extricate. The coil is going to be useless so unwind it.

Rewind 20 turns of #20 wire on the torroid and measure its inductance. This will allow you to "characterize" the torroid's A! With the Al you can determine the number of turns in the primary which meet the minimum inductance of the primary. (see amidon's website for the equations).

Wind to your heart's content. I now have a nice +/- 24 VDC supply. A PC torroid is quite happy carrying the load. Thanks also to Nat Semi's web bench which allows you to design supplies on the fly, specify the primary inductance, caps with Uf and ESR etc.

Hello

I am new to this newsgroup.

I don't know if anyone can help me - I am building a battery valve AM receiver, DF96 RF, DK92 mixer, 2 x DF96 465 kHz IF and push pull audio. I am using the Denco DP coils. It works really well on the broadcast bands but there is a strange from of instability in the mixer on the 10 MHz to 30 MHz band, particularly at the higher frequency end. At certain, very well defined positions of the tuning capacitor the mixer becomes unstable and very microphonic. Tune slightly off and it goes away. It receives very well on this band including CB and amateurs. If anyone has any ideas on the instability and how to cure it I would be most grateful.

TIA

Simon

Where to find octal sockets? One good source, especially for
homebrewers, is an electrical supply house. Octal sockets are commonly
used for power relays and come in a "surface mount" style perfectly
suited for one-off construction (no hole punching required). These
sockets were not intended for tubes or FT-243's, but they fit perfectly
and work just fine.

From my point of view, maybe your mixer is auto-oscillating for certain variable capacitor values. For a good diagnosis and troubleshooting try to connect a scope or better if you have one, a spectrum analyzer on the IF transformer with the higher impedance you can (probe or resistance divider).

The cure could be a simple low value damping resistor (in the dozens to hundreds ohms range) in the grid or/and plate path of the mixer tube.

Let's wait the other comments.

Message-ID: <zuW77.9$XK5.47008@news.ntplx.net>
Source record: 51258

I bought an optical encoder for an antenna project without realizing what the output would be. There are two TTL outputs with quadrature phasing, with the phase dependent upon the direction. While I could probably come up with a circuit to give a directional indication, I'd rather not reinvent the wheel. A quick web search suggested there are ICs available to do this now. Only trouble is that I can't seem to find a part number. Anyone know of an IC for this, or perhaps a circuit with a couple ICs?

Thanks es 73, Michael, KC1SX

In analog filters, windowing in the frequency domain reduces the envelope group delay peaks at the band edges. The "transitional to -6 dB" type is a good one.

Another approach is VLF (eg 50 kHz) cascaded double-tuned IF amplifier stages. I have had much success with this approach. A few stages like this approaches the Bessel group delay response, which is excellent for SSB/CW.

Some of the worst ringing filters I've seen were on a W-J HF-1000 with DSP. These are "brick wall" linear phase filters. The problem here is the brick wall amplitude spectrum. Take the Fourier transform of this kind of boxcar response and what do you get? Sin(omega*t)/(omega*t) where omega is the filter width. That rings like crazy for small omega. I was able to get much better CW reception of low noise signals using the 1 kHz filter on the W-J followed by a Gaussian passband passive LC audio filter in the audio output line. After discovering this I sold the W-J. If digital filters were designed with better amplitude spectra they would be great filters. Ulrich Rohde discusses this in "Communications Receivers".

4465. Soldering SMDs

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-26 16:22:52 UTC
From: Michael Wichmann <wichmann@sas.upenn.edu>
Message-ID: <9jpg82ptt1@netnews.upenn.edu>
Source record: 51261

Hey Everyone,

I was wondering if anyone had experience with soldering SMD chips like 144pin TQFP or similar. Also, how can one possibly solder J leads ??? Are there any other techniques than the usual 'by hand' approach one could do at home. (like solder bath .. how does that work anyway?)

Thanks,
Michael , AA3VM/DB6MG

4466. Re: Equiv BW of Xtal Filters

Newsgroup: rec.radio.amateur.homebrew

From: ritter@io.com
Message-ID: <3b603fa3.1306543@news.io.com>
Source record: 51262

Hi Bob, and others!

Presumably my stored-energy conceptual model of filtering is in fact wrong, but I still cannot see why.

On Thu, 26 Jul 2001 00:04:59 GMT, in <L8J77.148028$qs5.23791307@news02.optonline.net>, in rec.radio.amateur.homebrew "Bob Camp" <bob@cq.nu> wrote:

>Hi Terry,
>
>What's missing is that the filter in question is a digital filter
>rather than an analog filter. That lets you do some things with the
>delay response that you could not do without a *lot* of effort on an
>analog filter.

I agree that digital signal processing can do some things more conveniently, can be more easily adjusted to ideal performance and is more stable. Still, there is nothing magic about the math. I think the accumulation of value from multiple cycles seems analogous to the accumulation of "energy" in a resonant physical system.

>As an analog bandpass filter gets narrower you do get ringing due to a
>number of causes, one of which is the Q of the components. Another
>contributor is the tradeoff between a good steep cutoff and an
>increase in phase error over the passband. If you want to get rid of
>the effect with analog parts you build a delay equalizer. Think of it
>as a flywheel that you make run backwards. If the phase response is
>flat (equal delay) then a pulse will not be stretched extra much by
>the filter.

Over time various articles in the Ham literature have sought to eliminate ringing in analog CW filter (both crystal IF filter and opamp audio filter) designs. Delay equalization is not impossibly difficult, yet I am unaware of even one description of that being the road to non-ringing success. So I think the reality is more complex.

It is my understanding that the main advantage of delay equalization lies in the reception of modern digital modulation techniques which are especially sensitive to such delay. (Also, the amount of delay is an issue in AGC loops, but I don't know that one can have a filter without also having delay.)

>With some forms of digital filter you can play with amplitude response
>and phase response independently of each other. That makes it *much*
>easier to get things that do not ring a lot.

I don't at all doubt that a digital filter can be easier to adjust and have more distinct parameters, nor do I discount the advantage of mathematical models which can be far more complex than we might consider for a linear design. I just think that the math models effectively accumulate value similar to the way resonant systems accumulate energy.

>In either case though you still have the problem that if you hit the
>filter with a pulse it will block for a period of time that gets
>longer as the filter gets narrower. Since it only blocks for one cycle
>it's not technically ringing, but it is a period of time that you
>don't get a lot of useful stuff out the other end.

I guess something is unsaid here. In my experience, any filter that is shock excited generally rings for longer than one cycle. The number of ring cycles (at decreasing amplitude) is a function of Q, but the ring time is also a function of frequency (more rings at a high frequency may last as long as a few rings at a low frequency).

I hope for an insight which will give me a clearer model.

Terry KF5MH

An expensive, but still fairly popular solution is the Agilent
HCTL-2000 family of ICs:

http://literature.agilent.com/litweb/pdf/5965-5894E.pdf

Lower cost parts are available from US Digital (Made by LSI/CSI)
see

http://www.usdigital.com/products/ics.shtml

(I've used the LS7083/4 type parts.)

Lucky Me,

No antenna restrictions here.

I can add some ideas for you.

I met a fellow with restrictions like you have. he was on the ground floor and was allowed to erect a flagpole outside his front door at the far end of the sidewalk. The flagpole was made of heavy PVC pipe, flew the flag, and concealed a wire vertical antenna inside. He buried the feedline from the house at the same time he buried wires for the low-voltage light at the base of the flagpole.

Good luck to you & 73

Hi,
I've just found an old SAA5050 character generator in my junk box and I'd like to put it to some use. I've been told that some amateur radio enthusiasts have been using them? Anyone care to send me some info? I've got the datasheet, but I'd like some form of reference design that I can base my own stuff around. Is it as simple as hooking up a 6MHz and a 1MHz clock, hooking an EPROM's data lines up to the 5050 and wiring a 4040 up to the EPROM and the 5050's 1MHz clock? How about power-on-reset and stuff like that?

Thanks.

I used to do this by hand at times in the aircraft industry. It can be
done with a very fine tip soldering iron, but for good, reliable joints
you really should do it under a microscope of about 20-30 power. It's
amazing how much easier it is that way. I've done IC's with upwards of
100 leads with no trouble. Just takes patience.

And maybe Nope!

It depends what mode of transmission.

On SSB, if you used a speech inverter, you would simply transmit on the
'wrong' sideband (not illegal in the UK), and could easily be resolved.
You would also appear to be about 3kHz off frequency.

On FM, you would, of course, sound inverted.

On AM, you would also sound inverted, but could be resolved by taking
the signal as SSB, and tuning to one of the sidebands.

4475. FM Multiplex Generation

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-26 21:20:08 UTC
From: antonelron@hotmail.com
Message-ID: <ea82a75b.0107261320.40dccb51@posting.google.com>
Source record: 51271

This has nothing to do with the amateur radio service, but I thought I'd ask here anyway.

Can a FM composite generator giving FM stereo to broadcast standards be built? Without bizarre construction practices. Or, can they be bought and where.

A reference to a construction article would be helpful, if the finished product gives quality results.

Another method that works well is tinning the leads and pads;
then use a hot plate or a heat gun to achieve reflow temperature.

This method requires a bit of practice but is very reliable.

Application of additional flux will be necessary unless you use a
solder paste on the pads.

You could reach for your handy-dandy PIC programmer (or
whatever other microcontroller you like) and solve the
problem with one microcontroller and very few lines of
code. A friend and I did this in about five lines of
code on a Basic Stamp, as a prelude to driving a DDS
chip with a shaft encoder...

Hi Michael,

How about a D flip flop (4013) with one channel to the clock and the
other to D in. When the clock leads the D, Q(output) goes low (one
direction) when D leads clock, Q goes high (opposite direction).

Cheers,

Steve W

Hi,

So what is ringing anyway ?

One way to look at it is that this is what the filter does when you hit the input with a very narrow pulse of high amplitude. In general you worry about lightning and that sort of stuff making a filter ring.

Oddly enough that pulse excites something called the impulse response of the filter. The best you can do is to have a single "thump" when the pulse hits the filter. Something must come through since you punched the input and the least you can get through is a single pulse out. The width of the pulse will be a function of the bandwidth of the filter.

Since there is a "best case" performance here what you want to do is to get as close to that performance as you can. Anything that delays the energy in one part of the passband more than in another part of the passband will stretch out the pulse. If the delay is long enough you will get a ring.

The other part of the story is that there is an amplitude response that results in a single pulse output. The amplitude response you want transitions gradually from passband to stop band. You need to do both amplitude and phase correctly to get a best case result.

The reason you see all of this in relation to data stuff is that they are willing to make the trade offs involved to get good response in this regard. One major tradeoff is that the shape factor of a filter like this is not very good at all. A second tradeoff is that since you are devoting poles in the filter to equalization rather than filtering the complexity of the filter is much higher for a given bandwidth. The net result is that first you pay for a 16 pole filter and get an 8 pole filter, then your 8 pole filter works about as well as a two pole. At $10 a pole that gets kind of expensive.

In many cases the tradeoff in amplitude performance is simply to much to tolerate. In these cases you go for the amplitude response you must have to make things work and then delay equalize the result. You do not get rid of ringing but you make it as small as you can.

As has been mentioned elsewhere you still may have a lot of ringing if the amplitude response transitions quickly. If you have a JRC-545 handy you can check this out real fast by switching from the "loose" to the "tight" filter characteristic. The "loose" one has a gentle transition and it does not ring as much. Both filters are delay equalized.

Getting back to the Q thing. Think of it this way. What counts is not the Q of a part sitting by it's self on the bench. What counts is the Q of the part after it's in a circuit. You can *always* make a low Q part out of a high Q one if you have enough resistors on hand.

To make it easy assume you have a 10 MHz center frequency and a 100 Hz bandwidth on your filter. You blast the input and the output pulse is going to be some chunk of 100 Hz wide. That works out to roughly 100,000 cycles at 10 MHz. If you are working with fundamental filter crystals their Q probably only starts out around 250,000 at best. All you need to do is run them into a load that is roughly twice their motional resistance and the ring from the Q is taken care of. Since the motional resistance generally will be 10 ohms or so that's not going to be to tough in a 50 ohm filter.

Fun Fun Fun

It doesn't really count. It should detect the direction of even a very
small rotation if the encoder has any decent resolution.

> It doesn't really count. It should detect the direction of even a very small rotation if the encoder has any decent resolution.

I'm missing the intent, then. Wasn't the request for a quadrature detector to determine shaft position?

How can just a D-Flop do that? How can a D input (phase 1) change, without a clock input (phase 2) change (in fact, only a rising one), affect the Q output? Direction is only part of the solution and this solution only determines direction for rising edges of only one phase. That's not enough.

A quadrature detector is a four-state machine that must count bidirectionally at each edge change of both phases. The simplest discrete design required four D-flops, a fast clock and two one-of-four selectors to produce separate up-count and down-count pulses a few years ago. Such a design is now embedded in one chip, but I think the logic remains the same.

I'm going to step in here very cautiously. Filter analysis and synthesis can get pretty hairy, and it's been a long time since I studied it academically. So if any of what I say isn't quite right, I hope someone will correct it.

The transfer function of a filter can be represented by poles and zeros on the complex plane. From this, you can derive both the time response and the frequency response. Most useful filters have multiple pole pairs, and elliptical and some other filters also have pairs of zeros. I don't know of a good way to assign a value of Q to a filter with more than one pair of poles, although you can find the Q of each pair individually. So it's hard to generalize about a filter's characteristics based on a single value of Q, unless it's a second order filter having a single pair of poles.

If you look at each pair of poles individually, you can see that the Q increases as the poles get closer to the imaginary axis. In the time domain, the imaginary component tells you the frequency the pair of poles will ring at when struck by an impulse, and the real component (the distance away from the imaginary axis) is the inverse of the time constant of the envelope of the damped sine wave impulse response. If the poles are close to the imaginary axis, Q will be high, damping low, and the impulse response of that pair of poles will ring for a relatively long time.

In real filters, poles (and sometimes zeros) are distributed in various ways to get particular characteristics. To get a Butterworth, the poles are distributed around a circle centered on the origin. For a Chebyshev, they're compressed more toward the imaginary axis. Butterworth lowpass filters tend to have roughly 10% overshoot when hit by a step, and don't ring for very long. I've found Butterworths to be satisfactory for CW filters. Chebyshev filters have steeper skirts in the frequency domain, but more overshoot and ringing in the time domain. The higher the ripple in a Chebyshev filter, the steeper the skirts but the worse the time response. The Bessel or Gaussian filter has a maximally flat phase delay, and doesn't overshoot at all when hit with a step. But it has very sloppy skirts in the frequency domain.

I don't know a rigorous way to equate phase response with time response, except to say that in general, the faster the phase varies with frequency, the more ringing you'll see in the time response. And in general, rapid phase variation goes along with steep frequency response skirts.

People who design filters for a living have told me that the most effective way they've found to make filters which are both sharp in the

frequency domain and have reasonable transient time response is to make something like a Chebyshev or elliptical filter, then add allpass sections (which have essentially flat frequency response but phase response that doesn't vary linearly with frequency) to improve the time response to an acceptable level. This approach apparently produces filters with the fewest sections that have acceptable characteristics.

It's been mentioned that the math is the same for digital filters as for conventional ones. Well, yes and no. For example, it's possible to design a non-causal digital filter. That's a filter whose response begins changing before the excitation arrives. You could design a digital filter with a nearly a brick-wall frequency response. This has a sin x/x time response. In the theoretical case, the output begins changing an infinite time before the impulse arrives, producing the first half of the sin x/x response, and is at its peak just when the impulse arrives. In practice, the filter output is zero until the ideal response is at some chosen minimum level, resulting in nearly the same effect. Of course, there's no way you can really get an output before an unknown input arrives. But by accumulating and storing the input data, you can get the same result, just delayed a bit in time. I really don't know what all you can get by making a non-causal filter, but this is one example of a digital filter you can't make with real analog components. There are also a bunch of nonlinear things you can do with digital filters that you can't do with analog ones, and linear digital filters you can't make with analog components simply because of loss, size, and tolerance limitations of real analog components.

I'll part with the thought that the frequency response of anything brings with it the implicit assumption that the excitation has been applied forever -- in practical terms, long enough to reach "steady state". If this time isn't a lot shorter than the duration of the signal you're working with, then frequency response doesn't tell the whole story, and you've got to consider the time response. Most audio filters are in this category when the excitation is CW. I've listened to a lot of narrow audio filters that ring horribly when hit by moderate to high speed CW, and have designed and built ones with equal or better frequency response that don't noticeably ring at all. It's all in where you put those poles.

The November 1968 article by Wes Hayward is indeed the piece that launched the DC revolution. It's a classic.

You might take a look at "An Optimized QRP Transceiver", in Aug. 1980 QST. It addresses several common DC receiver problems including AM breakthrough. At least hundreds, and maybe more, copies of this rig have been built and used. Other articles that would interest you are "The 'Ugly Weekender'" by Roger Hayward KA7EXM and Wes Hayward W7ZOI in Aug. 1981, and "High Performance Direct Conversion Receivers" by Rick Campbell KK7B in August 1992 QST. Rick has written several excellent articles since, in QST and I believe QEX. Any you can find would be worthwhile reading.

> . . .

> filter circuits. Thoughts?

You can use either a passive or active filter. The "Optimized" receiver uses an active filter, Rick's receivers use passive filters. One caution is that if you use a passive filter, use small inductors, preferably shielded, and/or take care to keep them well away from transformers and

other sources of strong 60 Hz fields.

> I used some ordinary switching diodes in the mixer. Does anyone think
> that
> the RX would work significantly better if I replaced them with the
> recommended Schottky diodes?

I ran experiments to see what the difference would be, and couldn't find any. Schottkies might give a little better noise figure, but not enough to make a difference in an HF receiver. The higher threshold of silicons probably increases the AM breakthrough threshold, and they seem to be inherently better matched. I use silicon diodes exclusively.

> shielding?

The main problem with VFO radiation was pointed out by W7ZOI years ago in a Technical Correspondence piece -- "peakable hum". VFO radiation can get into a power supply, where the diodes mix it with 60 or 120 Hz, creating an RF signal offset from the VFO by this amount. It sounds like hum, but if you have a tuned front end, you can peak it up with the signals (since it's really RF). It's often conducted to the power supply by the DC receiver power supply leads (when running from an AC supply), and a cure is to run the leads in a bifilar fashion several turns around a ferrite core. 70 series is best for this, with type 43 being ok also. More problems are usually caused by common mode currents in the ground plane or board traces than by radiation. Shielding won't help the ground currents.

On your web page it says:

"It takes a long time to file the gap into the toroid; your needle files
will get dull. Don't push too hard, as ferrite is fragile. You want a
narrow gap on the outside part of the ring, so file from the inside. A
gap about the thickness of a fingernail is good. Depending on the
ferrite material, this sniffer should be good for HF and VHF."

Might I suggest a Dremel tool with a cut-off wheel instead of a file? I
haven't actually used one on a ferrite, but those cut-off wheels will
cut the hardest steel, so ferrite should be a cinch. Worth a try
anyway.

4494. 17mtr DSB: receiver refinements

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-27 10:44:59 UTC
From: n2cqr@clix.pt
Message-ID: <3b61460b.2440976@news.clix.pt>
Source record: 51287

I'm having a lot of fun with the DC receiver that I built as part of my
evolving 17 meter DSB transceiver. (I've posted pictures and a schematic
at http://planeta.clix.pt/n2cqr Just click on the 17 meter DSB link.)

Right after I built the receiver, I was browsing through some old QSTs and
came across the November 1968 issue. Wes Hayward, W7ZOI, and Dick Bingham,
W7WKR, had an article entitled "Direct Conversion - A Neglected Technque."
This must have been the piece that launched the DC revolution. Neglected
no more! I knew I'd been on the right track when I discovered that the RX
described in the article was very similar to the one I'd just built. Same
product detector and AF AMP. (This came as no surprise as I'd taken the
circuitry out of SSD.)

My previous experiences with DC RXs were pretty bad -- lot's of AM
breakthrough, common mode hum, etc. I think I avoided many of these
problems with this RX by staying away from the standard NE602-LM386
neophyte designs. And I've been helped by the fact that earlier rigs were
built for 10 an 7 Mhz, where SW broadcast interference is much more intense
than at 18 Mhz. The AC hum problem was cured with one toroid between the PS
and the rig.

I have had some problems with AM breakthrough. On Sunday morning at 0800
UTC, Radio Exterior de Espana fired up, apparently with its antennas aimed
in my direction. I consulted their schedule and I think I was hearing
either their 17.77 or 17.88 Mhz broadcast. Too close for comfort. Pretty
much wiped out the ham signals I was listening to. I went back and very
carefully re tuned the two tuned circuits in the RF amp (front end). I
found that I could peak the both of them in such a way as to eliminate most

of the AM breakthrough problem. I know many people advise against RF amps
ahead of the mixers in DC receivers, but I wanted to get the two tuned
circuits in there. I'm glad I did.

The RF amp can, however, give me too much gain and make things very noisy.
I've seen people use 10K pot as an attenuator at the antenna port, but I
came up with what I think is a more elegant solution: I put a 2k pot on
the 12V line going to the MPF-102 in the front end. So I can control the
voltage going to the the drain of the grounded gate amp. This serves as a
very smooth RF gain control. I use it a lot.

The receiver is stable and sensitive. Of course it is very broad and I
hear "both sides." But I'm very satisfied. There is, of course, still
room for improvement.

I'm still using the headphones. The rx is working so nicely that I'm
reluctant to add the extra stages needed for speaker ops. But I suppose
I'll eventually give it a try. I don't even have an audio gain control.
(The RX in the Nov. '68 article didn't have one either. The authors
suggested detuning the caps in the front end if you needed to reduce
gain.)

One deficiency I can hear involves very strong SSB signals. Even if they
are completely out of my tuning range, I can hear the "monkey chatter."
Tuning the RX does not affect the sound. Same chatter no matter where I
tune. Anyone have any thoughts on how to cure this? I don't know if the
stations involved are splattering or not. I'm thinking that a low pass
filter between the detector and the audio amp might help. I'd be looking
at a simple, passive filter -- I don't want to put in any complex active
filter circuits. Thoughts?

I used some ordinary switching diodes in the mixer. Does anyone think that
the RX would work significantly better if I replaced them with the
recommended Schottky diodes?

I'd been thinking that I'd need a lot of shielding around the RX board
to
make this thing work properly, but so far it is working fine with no
shielding. The VXO is in a box, so I suppose that helps with some of
the
problems often seen in DC RXs. Anyone think I should put in some more
shielding?

Be careful where the ferrite dust goes.
I used an off brand Dremel type tool that had a DC motor, While cutting
some ferrites the tool quit working. Upon disassembly I found the permanent
magnets were covered with metal powder that interfered with rotation.
I never did get it working again.

We've been doing this at MMT for about 10 years now. A macro scope helps but what you need to do is center the part as good as you can and hold it down with one hand. Then coat the leads with liquid flux then get a drop of solder on the end of your soldering iron and run a "bead" along one edge. After the first edge is down the rest are easy. Over the last 10 years we have placed literally hundreds of thousands of parts this way. We developed this technique after a fab house wanted to charge us $55 a board to place 3 PLCC parts. We finally got a pick and place 2 year ago but we still have to do a few older boards by hand.

: This has nothing to do with the amateur radio service, but I thought
: I'd ask here anyway.

Hi Anton,
No problem..

: Can a FM composite generator giving FM stereo to broadcast standards
: be built? Without bizarre construction practices. Or, can they be
: bought and where.

Yes to both questions and some information. I've seen a number of articles on the web dealing with home built fm broad radio transmitters and their associated stereo generators. A web search via www.altavista.com or similar might be in order for that.

There are a number of kits around... Panaxis which is in Paradise, California sells many related kits. You can buy their stereo generator in kit or complete. You can also buy many other radio item kits there, they have a web page that a net search should find.

: A reference to a construction article would be helpful, if the
: finished product gives quality results.

I have one of their stereo generators in line now to my Sparta transmitter and it really works well.

Hope that helps
cheers

Nope. From the original, <zuW77.9$XK5.47008@news.ntplx.net>:

> While I could probably come up
> with a circuit to give a directional indication, I'd rather not reinvent the
> wheel.

I presume you can see how two D-flops connected as suggested can show the
direction of spin, given input from the encoder he specified.

Hi All

I regularly (10+ per day) solder 208 pin QFP chips and many other SMD parts. Easy to do with a regular iron. I use a Weller TCP, standard fine tip. All it takes is practice. Clean the area to be soldered with solder wick and reflow flux. The sticky flux residue (I use multicore "Red Jelly") allows for accurate positioning f the new chip. Tack two opposite corners and then solder along each side - it doesn't matter if you join the pins. When all sides are done, paint around with reflow flux and remove the excess solder until all pins are seperated.

A 208 pin QFP takes about 30 mins total the first time, but with practice 10 mins is reasonable. This method also puts less heat into the chip that the "tin the pins and remelt" technique.

Not as good as a proper SMT reflow machine but good enough.

Back in the mid-sixties, CQ magazine ran a couple of articles on "speech inverters". That was a time when you'd often see DSB transmitters or converters (DSB of course being specifically double sideband with a suppressed carrier). Since virtually no one was using a synchronous detector, the common means of receiving DSB was to use an SSB receiver and use it's filter to hack off the unwanted sideband. But older receivers were still common, and their IF filters left a lot to be desired when receiving SSB.

So CQ ran an article (and then a followup showing a way of doing the same thing with a different circuit) that was nothing more than a balanced modulator and an audio oscillator. It inverted the audio, and then you fed that into the DSB transmitter. The result put the lowest audio frequencies at the far points from the suppressed carrier, rather than right at that point. So you didn't need such a sharp IF filter to get rid of the unneeeded sideband.

Normal DSBsc

highest LSB USB highest
audio----------|-----------audio
|
Suppressed
carrier

inverted audio DSBsc:

```
lowest LSB USB lowest
audio----------|-----------audio
|
suppressed
carrier
```

In the first case, the resinserted carrier has to be exactly where the suppressed carrier is or else the two sidebands will translate to audio at different frequencies. Filtering out the unneeded sideband in the receiver allows for some variation of the beat frequency (the same way one can mistune an SSB signal with the only result being an odd sounding voice).

But if your filter isn't really great, as was the case in those old receivers, you couldn't knock out the unneeded sideband right at the carrier point.

With the inverted audio, you'd place the bfo at the "lowest audio" point, and the flaky filter would just let some other signal through (which could be annoying, but could be mentally tuned out unlike the sidebands beating together). Any of the unwanted sideband that did pass through the filter would translate to audio at a higher frequency, where it would be well away from the frequencies of the wanted sideband.

An interesting concept, and one that never got much coverage because the assumption was that you'd use a good SSB receiver to knock out the unwanted sideband.

I am pleased to enclose for your kind attention the “Announcement and Call for Papers” for Symposium on Maritime Disaster Management. The Symposium is being organized by the Frontier Guard General Directorate, Ministry of Interior, Saudi Arabia in collaboration with Saudi Aramco and King Fahd University of Petroleum and Minerals. It will be held at KFUPM in Dhahran, Saudi Arabia from 19-23 January 2002.

The Symposium provides a forum for dissemination and exchange of information encompassing a broad spectrum of topics related to management of maritime disaster. Special technical session, workshops, exercises and exhibitions and are being planned. It will encourage and facilitate the interdisciplinary communication amongst experts, researchers, scientist, government and academia, local, regional, and international agencies and industry.

Abstract are invited on the topics outlined in the enclosed brochure, and others which fall within the scope of the symposium .to register your interest as a participant or to submit an abstract for consideration, please complete the relevant forms(s) and return your submission without delay .we strongly encourage abstract submission without delay .we strongly encourage abstract submission by E-mail (please see the symposium broacher for further details).

Looking forward to hearing form you soon.

With best regards.

Dr.Abdulaziz M.Al-Suwailem

Chairman, organization committee

They have no ways of prohibiting antennas here but they do annoy you
sometimes. There are severas treatments:

1. Buy them and mount decent antenna instead of their indoor type with
amplifier

2. Build astable multivibrator running on 1 MHz (should produce
squares), hook it on 10W broadband amplifier and go on vacation.
One guy did it here but made mistake: powered from wall outlet - when
they did not found source (he transmitted into power lines) they started
disconnecting buildings and found device (when they unpluged power,
interferences disappeared, when they put back, they went back on).
Power it from car battery.

3. One of my chiefs was Duch and was HAM too. He had 2kW HF transmitter
at home. So he pointed antenna in his neighboor kitchen and waited. As
soon as neighbour's wife took glass pot in her hands he pressed key
causing neon lamps to glow for a moment. She scared off and broke the
thing dropping it on the floor.

4. I had constant problems with CB transmitter I used to talk with
friends. Solved by hooking wirewound resistor in series with modulating
transformer. Output power was not measurable *at least not with
available instruments) but radio was still usable within town.

I heard of such stories and to be honest I cannot believe that such
things exist.

Opto couplers are non-linear. But you can make them linear by taking two
of them and two OPAMPS. Put another optocoupler in feedback and you will
linearize it.

Take two 432 handheld radios, tune one on RX frequency and from it's
speaker output, and through external VOX device and attenuator in
MIC/PTT input on TX one. Use two antennas.

Here we have local repeater that works in that way for more than 15
years and very interesting is that nobody touches that thing at all we
had even trouble finding who knows where repeater was installed.

It's always a good idea to have as much selectivity ahead of the mixer as possible -- although I've gotten away with nothing but the transmitter's LPF. It's also good to have as little gain ahead of the mixer as possible to minimize AM demodulation from strong signals. If I interpret your question correctly, you're proposing leaving the common gate FET in place but without Vdd. I don't think this would be a good idea -- it's unlikely to provide the optimum coupling between your tuned circuits.

Putting all the gain at AF has its problems, too. You sometimes have to work hard to prevent audio feedback. But it can be done. And using an external AF output stage makes it a lot easier. But no matter what the results, you'll learn a lot in the course of experimenting.

Thanks for the great advice Roy. Experiments with the RX continue.
I'm starting to thnk that the RF amp ahead of the mixer might not have
been such a great idea. I put an amplified speaker (from a CD player)
after the 100 db amp and discovered that with all the additional audio
gain, I had to significantly reduce the RF gain. And the RX seemed to
work a lot better this way. My problems with the strong SSB signals
seemed to be reduced.

I like having the two tuned circuuits that came along with the
grounded gate amp in the front end, so I'm thinking of just building
in some more AF gain and taking the 12V completely off the drain of
the grounded gate RF amp at the front end. What do you think?

Homebrewed GG linear amp deck consists of the tubes, coils, band switch, meters, filament xformers, variable caps. With case but no HVPS. Uses external blower.

Was in use for several years, then several years idle. Not set up to check it in operation at this time but it worked great before it was shut down. 1kw+ out. Tubes just checked showing no inter-electrode shorts and filaments ok. Common GG circuit.

$175. Will split packing and shipping charges. Prefer pickup, location near New Haven, CT. If interested, can email photos.

Bill, I am a fan of RF attenuators before any active stages. You may want to consider adding some switched attenuators before the RF amp. I find cheap toggle switches work well enough.

The ARRL handbook shows the method. I'd make it maybe a 10 and two 20 dB switches.

Anyway, by kicking in 10 or 20 dB of resistive attenuation you reduce a host of sins.. Nearby signals are attenuated and so are out of band AM stations and such.

With passive resistors as the first attenuators you don't have to worry about overload.

Many electronic gain control methods have the bad tenancy of reducing their dynamic range as you are reducing the gain. This is bad since that is the time they are getting hit with strong signals !!!

Yeah, manual RF attenuator toggle switches can be a pain in some ways, you need to change them as the band conditions change, but I think the benefits outweigh the hassle.

Yes, G3VFP has designed one and even sells them now. He even has a design
using opto isolators for the CAT interface for the rig for TRUE isolation.

see www.qsl.net/g3vfp and follow the links.

Hello,

I was given a full set of the RCA vacuum tube databooks that date back to 1940. I really have no need for them and I am considering selling them. The only problem is I don't know what they are worth.

Does anyone have an idea of their value??

Paul

4521. FS: Homebrewed amp w/ pair of 4-400C's

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-28 17:50:19 UTC
From: nfn04028@naples.net

Homebrewed GG linear amp deck consists of the tubes, coils, band switch, meters, filament xformers, variable caps. With case but no HVPS. Uses external blower.

Was in use for several years, then several years idle. Not set up to check it in operation at this time but it worked great before it was shut down. 1kw+ out. Tubes just checked showing no inter-electrode shorts and filaments ok. Common GG circuit.

$175. Will split packing and shipping charges. Prefer pickup, location near New Haven, CT. If interested, can email photos.

They seem to get $3-8 on ebay individually. I'm sure somebody might be
particularly interested in a full set.

You could also use a PIN diode attenuator ahead of the front end. You would vary the attenuation by the amount of current that you run through the PIN diodes. Also, if you need any hot carrier diodes for you experiments, I could send you a matched set of 4. I don't have too many sets, so I don't generally send them out, but since you are experimenting.....
Anyway, give me a shout at my e-mail address, and I will be glad to help you! If you would like to go the route with a complete mixer instead, I have some Mini-Circuits mixers on hand.

I have taken this approach, using a 7474 flip-flop, with a 74123 one-shot, along with 74191s for tuning parallel programmable synthesizers. Gary Pershin came up with a good idea, using an XOR gate to eliminate the error when changing direction. Right now, I am using a PIC (16F84) to control the AD9851 DDS chip. If anybody wants the code, along with the schematic of the DDS, feel free to give me a shout. As for the code, I have to give credit to Mr. Jeff Woods on this one!

True, PIN diodes make good attenuators in general. They have some limits though. They can be overloaded and cause intermod in themselves particularly at partial attenuation levels.

Although they are likely to be pretty good in general. They make great hard on-off switches.

==========

And, due to carrier lifetime limits, the PIN diodes turn a lot closer to regular rectifier diodes below a certain frequency and that is usually quite a few MHz. So, AM broadcast may easily become rectified and add to the troubles.

The actual frequency where they start to turn into rectifiers depends on the specs for the particular pin diode, but all of them do it at some frequency....

Which is part of why I like passive resistor attenuators. They reduce interfering signals at ALL frequencies and you can put them in front of any tuned circuits.

PIN diodes are handy, but they ought to be used after some frequency selective tuned circuits to keep them honest. And only at frequencies above their carrier lifetimes limit....

You can use the MFJ-1278 with practically any packet BBS software. I have personally used it with MSYS software in the past (KISS protocal). I'm sure there are other hams who could testify to this fact. Good luck to your packet operations. I am running MSYS 1.20 beta on my MFJ-1274. I also used to run MSYS on our MARS packet station when I was in the Navy on our MFJ-1278.

4539. Help please, JFET Const. Current Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-29 16:42:40 UTC
From: davecomjkt@yahoo.com
Message-ID: <tm8f80jn4div6c@news.supernews.com>
Source record: 51236

Subject: Help please, JFET Const. Current Design

Fig.-1 below shows a circuit for a JFET Constant
current sink. I have found several sources for the
design equations shown below. But no derivations
for these equations.

I would like to know how to derive the design
equations (eq.1-3 below) for this circuit.
I am familiar with basic circuit analysis and
the low frequency small signal model for JFETS.
(I apologize for the poor ASCII drawing.)

Direct replys with in-group replies (so others
may benefit) are appreciated (my NNTP access
in Jakarta is spotty with poor retention).

Thanks in advance,
Dave in Jakarta, YB0ART/WB4ONA
davecomjkt@yahoo.com

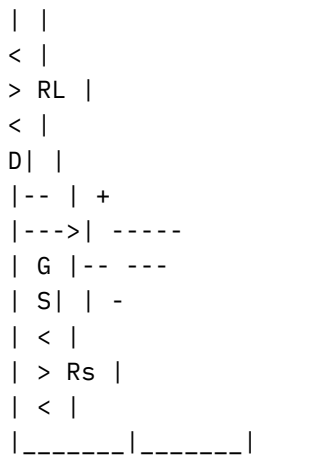

Fig.-1, JFET Constant Current Sink

Design Equations:

Vgs = Vgs(off)*(1-(Id/Idss)^1/2) (eq.1)

Rs = Vgs/Id (eq.2)

Rs = (Vgs(off)/Id)*(1-(Id/Idss)^1/2) (eq.3)

Notes:

1. "(f)^1/2" denotes "square root of (f)".

Mike,

US Digital (www.usdigital.com) makes a couple of them. Check out their LS7083 and LS7084. Simple 8-pin DIP solutions (inexpensive as well).

Gary

Hi,
may I suggest a video recoreder head. Just the head part not the whole drum,
this was used in a magazine project a while ago. You automatically get a
fine gap and coil already made up.
James.

4543. Binaural I-Q Receiver

Newsgroup: rec.radio.amateur.homebrew

Source record: 51240

The March 1999 issue of QST has a Binaural I-Q Receiver. Has anyone built this receiver? What is a source for the "Mini-Circuits" TUF-1, or SBL-1 mixer. Dan seems to be out of them. Also looking for a source of small steel plated chassis as this is Direct-Conversion Receiver.

You know why they replace them? I can think of several reasons. The biggest is that the manufacturer along with MSHA require the harness to be replaced after ANY fall. Thanks, but I'll trust my life to only a NEW harness. You don't know what a used one has been through.

Anyone for Russian Roulette?

Nah, they replace them on a timetable. I think that even a cursory
inspection will show worn or broken stitching or worn straps. Use
common sense. Besides, where is your "last chance" belay?

Russ

You are correct on that one, Jim. I should have been more specific, and mentioned to use a diode that has at least a 1.5uS minority carrier lifetime, such as the 1N5767. I know that in the past few years, Unitrode came up with a better device for the .2 to 30MHz range. One of the fellows back at Rockwell-Collins was doing some upgrades to the KWM380s, using the Unitrode device. I need to find out what the part number is, and try it out myself. I have been using the 5767s as steering diodes in my own receivers, but not as AGC devices yet. There was a real neat circuit that was being used in some of the Collins equipment using PIN diodes, and the receivers were able to handle several volts of RF, with no problems. When I left Rockwell-Collins, I left that circuit behind. You know, intellectual property and all!

Gee, I haven't seen such narrow belts in use for over 20 years... if you climbed for work with that thing on here in Oz, it would cost thousands in fines for employer and worker.

There is little doubt that a careful visual inspection (for wear, abrasion, damaged fibres, damaged stitching, sun damage, rot, chemical damage, water damage, strained fibres, deformed attachment loops / hooks, proper safety hook function, etc) will indicate whether it is might be suitable to use as a pole belt to lean back on (with the addition of a suitable pole strap)... but the supplied lanyard implies that it is intended as a fall restraint (even if the belt is so narrow as to risk injury in a fall), and that is a whole 'nother kettle of fish.

Ant then there is its heritage. Of course the user of a harness (if I use the term loosely) should condemned it (by cutting it up) if it sustains any fall, it is a bit hard to be certain isn't it?

Owen

BTW, Do you guys still use climbing spikes on your boots for climbing timber poles?

4552. Re: Help please, JFET Const. Current Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-30 13:44:13 UTC
From: Mike Allenson <mike@allenson.fsnet.co.uk>
Message-ID: <9k3oi9$qa5$1@newsg1.svr.pol.co.uk>
Source record: 51099

I had a go at deriving the equations.

Equation 1 represents the FET as a simple square law device where the drain current is proportional to the square of the gate -source voltage increment above pinch off, eg

Id = K1*(Vgs-Vgs(off))^2 (1a) where K1 is an arbitrary scaling constant.

K1 can be found because Id = Idss at Vgs = 0. Hence:

Idss = K1*(-Vgs(off))^2 (1b)

hence K1 = -Idss/(-Vgs(off)^2 (1c)

and 1a becomes
Id = (Idss/(-Vgs(off)^2)*(Vgs-Vgs(off))^2 (1d)

rearranging to give Vgs as the dependent variable, gives:

Vgs = Vgs(off)*(1 - (Id/Idss)^1/2) (1e)

Which is Eq 1

Equation 2 simply represents the fact that in the circuit Vgs equals the voltage drop across the source resistor.

Equation 3 substitutes for Vgs in eq 1 from equation 2 to give the design equation for the Rs for a required Id.

Rs = (Vgs(off)/Id)*(1-(Id/Idss)^1/2)

(N.B holding on to the -ve sign for Vgs(off) in eq 1b and onward may seem strange given the term is squared. This makes sure that the Vgs range over which the model is valid ie only for Vgs between Vgs(off) and 0 is maintained.)
I hope this is helpful.

If the "first sign of trouble" is an accident, then someone has not been
looking for trouble like they should; i.e. inspecting the safety belt
and lanyard before each use. This kind of equipment is designed so that
defects are readily apparent, but you do have to take a moment and look
for them.

There may be a lot of Darwin Award nominees.
This really sounds dangerous to me.

> - Do not use a nonpolar electrolytic cap for this task--it doesn't have
> enough heat-dissipation capability. Get an older-style oil-filled cap.
> It is a lot larger, but it isn't going to blow up on you.

Main thing about cap - it should be AC motor work capacitor (NOT START,
START CAPACITOR ***WILL BLOW*** in your face).
Such capacitor can stand a bit of everything such as asynchronuos
generator reactive excitation and substituting phase when running
3-phase motor on single phase network (approx. 10uF per 100W of power),
Power factor correction capacitors are also good.
Any X2 (Across Network) type is good (it can stand its own reactive
current, with battery it will be smaller) provided that you can build
sufficent capacitance (they are smaller).

Using variac is definitely safer, also using ballast inductors may help.

But anyway, this is QUITE dangerous as I can see. If capacitor melts in
short circuit and you are not properly fused you may get "little"
incident with battery.

From what I can see switching reactance produces delta pulses which
cause battery to ring on its own frequency (as described in desulfator
mentioned earlier) just feeding more energy into it. I prefer slower
process done by desulfator. This may cause overload and overheat of
desulfated part of plate.

But anyway I have spare badly sulphated battery available. As soon as
somebody stays with me (SAFETY SAYS:do not do such things alone) I will
try it.

> > ... about five lines of code on a Basic Stamp...
>
> Love to see that code. How fast can the Stamp track motion?

Here's the main loop, plus supporting definitions:

```
Symbol EncoderI = Bit0
Symbol EncoderQ = Bit1
Symbol TurnTest = Bit2
Symbol InputI = Pin1
Symbol InputQ = Pin2

StartHere:
gosub DDSInit

MainLoop:
EncoderI = InputI
EncoderQ = InputQ

BusyWait:
if EncoderI = InputI and EncoderQ = InputQ then BusyWait

TurnTest = InputQ ^ EncoderI
if TurnTest = 0 then LoopUp
goto LoopDown

LoopUp:
gosub DDSUp
goto MainLoop

LoopDown:
gosub DDSDown
goto MainLoop
```

As for speed, it was more than fast enough driving a
Q2220 DDS chip (parallel input) through an interface
wire-wrapped from TTL logic chips (long gone, so please
don't ask for schematics). An earlier version didn't
read the encoder at the top of the loop and sometimes
got confused when it missed transitions.

Thanks Mike for your reply. I took a look at this a bit closer. I derived the equation for Rs directly from the equation for the FET Vgs vs. Id transfer function:

Write the equation that defines the FET
Vgs vs. Id transfer function:

Id = Idss[1-Vgs/Vgs(off)]^2 (1)

Solving eq. (1) for Vgs:

Vgs = Vgs(off)[1-(Id/Idss)^1/2] (2)

Now, Vgs = IdRs (3)

Solving eq. (3) for Rs yields:

Rs = Vgs/Id (4)

Combining eq.'s (2) & (4) we obtain an
expression for Rs in terms of Id:

Rs = (Vgs(off)/Id)[1-(Id/Idss)^1/2] (5)

Best Regards, Dave

J M Noeding wrote:
> you only needed half amount of cells for a British car......

Terry says: PRESUMING YOU MEAN 6 VOLT?
Not the British cars we had!
Many have always been 12 volt. Until about 1958 my family had a couple of 1930s Lanchesters that were 12.
Six volt may have been used in the small British Fords and maybe some Vauxhalls? Both these companies being US subsidiaries?
Also I do have a vague memory of some twelve volt vehicles with positive to ground (as opposed to today's normal negative to ground/chassis) system. This meant some auto radios had options for either polarity IIRC. Anyone remember this?
The reverse in fact; when I arrived in Canada in the mid 1950s all older US/Canadian vehicles were six volt. Today most vehicles are twelve, or in some cases twenty four. Rarely but still see the occasional six volt old car radio at junk sales.
BTW twelve volt CBs in twenty four volt transport trucks eh? Then they wonder why they don't last!
The only six volt car we ever had was one which had been retrofitted with a 1938 Bedford straight six engine. Bedford was the equivalent of GMC (General Motors). The six volt system of course meant that the current was twice what it was with the original twelve volt system and the wiring was inadequate! So I rewired the whole vehicle, which was incidentally a 1926 Daimler hearse we used for camping, using war surplus items. The cabling to a rear terminal block had a braided cover and was from a British armoured vehicle; the headlight switch was from a US transmitter tuning unit etc.etc. Great fun!
Incidentally I borrowed a much used GMC pickup, a straight six with column shift, during the 1970s and opening the hood to disentangle the shift linkage found that the valve cover of the engine looked identical to that of the 1938 Bedford that I had worked on 20 years earlier!

4563. Info CI-V or DB25 Interface for IC271H

My very first job, back in 1959, was repairing car radios. I do recall
cars with six volt, positive ground systems, but can't recall 12 volt,
at least not in the USA.

It was not unusual for someone to bring their car in because the radio
wasn't working and I'd find they had just replaced the battery and put
it in backwards. Oddly, everything in the car worked ok with the
reversed polarity - gauges, starter, other motors, etc, - but not the
radio. I'd reverse the battery, replace the fuse and off they went.

Hadn't thought about that in years, but there you are.

4565. Tayloe Detector / Polyphase SSB questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-31 13:01:41 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <9k6a89$2n6qe$1@ID-61331.news.dfncis.de>
Source record: 51112

I'm interested in views on the following questions.

Considering a receiver consisting of input tuned circuit, Tayloe detector, polyphase audio phasing network, and audio filterting/amplification:

1. Is an RF amp necessary/desirable ahead of the Tayloe detector? Or am I right in thinking that you want to minimise IMD products by doing all amplification after the detector?

2. Sometimes people use 2x clocking, sometimes 4x clocking. Presumably if you use 2x it is important to get an exact mark/space ration of 1, which could be difficult, particularly in a multiband receiver. Is the 4x clocked version therefore always superior to any 2x clock design?

3. I have seen a few circuits using the Tayloe detector followed by a phasing network. In some cases, people subtract the Tayloe 0 and 180 outputs, and the 90 and 270 outputs ahead of the phasing network. E.g. "QRP2001 Receiver" in Sprat #101. Why? Why not simply feed each of the 4 Tayloe outputs directly into the polyphase network as in G3OGW's 4-path Polyphase D-C receiver (Tech Topics, RadCom May2001). The 4-path method is said to give big improvements over 2-path by cancelling the unwanted sideband inside the polyphase network, this reducing errors / component tolerance sensitivity.

4. Is amplification needed between the Tayloe detector and the phasing network? I understand the input to the phasing network should be low impedance, and the phasing network likes to drive a high impedance load at its other end. So can one just put 4 unity-gain low noise op-amps before and again after the phasing network? In that case all the gain in the receiver would be in the subsequent AF stages.

5. On the subject of the phasing network itself, all phasing networks I've seen use a fixed value of resistor in every stage, with different capacitance values in each stage. Since close-tolerance resistors are a lot more easily obtainable than close-tolerance capacitors, doesn't it make more sense to use identical value capacitors throughout the network? Then you can buy a large number of the same capacitors, and select close matching sets of 4 for each stage.

To all,

Rig Builders GE Ham News (1-48) is now on K4XL's
-=Boat Anchor Manual Archive=- (BAMA).

http://bama.sbc.edu/

This 1948 issue of GE Ham News has great charts for comparing various
tubes
and circuits for Drivers, RF Amps and Modulators. This is needed if you
are considering building a new-old rig, or working on an old homebrew.
I
found it in an old estate and thought the information was needed. I
scanned it at 300 dpi for good resolution in printing. It's 565kb, for
all
8 pages. It prints and looks good at 8-1/2 x 11".

(Note the directory at BAMA might change. ???? Right now it's on:

ftp://bama.sbc.edu/downloads/ge/hamnews/ Click on 1-48.pdf

exact link is ftp://bama.sbc.edu/downloads/ge/hamnews/1-48.pdf

4567. Future Supply of Motorola RF Transistors?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-31 13:29:24 UTC
From: chris@kessell.com
Message-ID: <c83ba15.0107310529.7b66724e@posting.google.com>
Source record: 51114

Motorola recently sold a chunk of their RF transistor portfolio to M/A-COM, including the very useful MRF141G/MRF151G 300W power transistors, and no longer provide any support for them (all datasheets etc. have been erased from their website). It is also unclear whether M/A-COM are going to bother to continue making these parts.

Can anyone shed any more light on the situation, or knows of any good alternatives to the MRF141G/MRF151G devices?

Chris

Wow... Seems like it would have been far easier to convert to a 12v
system. Usually those conversions aren't too involved. Of course,
the more electronics the more interesting the conversion. :)

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3B66FDF1.A7189AE4@eznec.com>
Source record: 51119

The only problem with using this circuit and this approach is that you have to know the Vgs(off) and Idss for the particular transistor being used. Both these parameters typically have a wide tolerance (sometimes a 10:1 ratio for Idss) for a given part number. If you're going to build a single unit, you might as well just tweak on the resistor value since it's easier than measuring Vgs(off) and Idss. If you're going to make a lot of units, you'll have to measure each individual transistor, and use a different resistor for each one, or start with a big pile of transistors and select devices for a narrow range of the important parameters. When designing circuits for mass produced products, I've never used a FET for a current source because of this problem, but a bipolar transistor circuit instead.

Chrysler products had a positive ground up at least into the '50s. I know GM cars were always negative ground, and I believe Fords were too. I vaguely recall that some British Leyland cars of the '60s -- MG, Austin, and so forth, had positve ground, but I might be wrong about that. And I had exactly the same experience as Bill -- a radio that didn't work, and which had a blown Ge PNP output transistor. It was in a Chevy Corvair which had a recently replaced, reversed, battery. Most of the gauges didn't work (I don't think it had many), but it started and ran.

4574. Coax coil?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-07-31 19:57:45 UTC
From: Terry S <tsanford@nf.sympatico.ca>
Message-ID: <3B670DB9.8237A30B@nf.sympatico.ca>
Source record: 51121

I recall a magazine article about oscillator circuits which used
specific lengths of coax as the frequency determining item. Instead of
coil-capacitor resonant circuit.
The article mentioned the formula e.g. a quarter wave open circuit or a
quarter wave short circuited at 'far end' etc.
A trimming capacitor was mentioned too which could vary the frequency
slightly, IIRC.
Any one recall this or be able to give a source of info?
Terry.

Sylvan:
These days yes it would be. But back in the late 1940s with a vehicle that had had it's original sleeve valve engine removed and a 1938 Bedford straight six stuck in, so it could be kept going as an ambulance and hearse during the blitz (air raids), no!
Back then most North American vehicles were still six volt; at least those we saw in the UK. And you have no idea of the shortages and the rationing that we had to endure even years after W.W.II.
God Bless Uncle Sam for the 'Marshall Plan' though.
BTW we used to hand crank the Bedford because the one an only six volt battery we had was flaky! Happy times!
Terry.

An open circuited quarter wave line or shorted half wavelength line looks like a series resonant circuit, and a short circuited quarter wave or open circuited half wavelength line like a parallel resonant circuit. You can replace part of an open line with a variable C to make it adjustable. There are two down sides to this approach. One is that the lines are "re-entrant" -- unlike lumped constant resonant circuits, they become resonant again at odd harmonics. So there's a possibility that an oscillator will oscillate at one or more of those other resonant frequencies. The other down side is that the Q of transmission line resonators is mediocre at best. This means you won't be able to make an oscillator with good phase noise characteristics, and probably not with good frequency stability, using transmission line resonators. Still, it's a useful technique under some conditions. I've used transmission line resonators for a 6 GHz power oscillator in a low power motion detecting radar. Phase noise and stability weren't a problem, microstrip transmission lines are small and cheap, and alternative approaches were a lot more expensive.

I agree. It's also possible to use an adjustable voltage regulator eg LM317 to
provide a constant current supply. Only one resistor R is needed in addition to the LM317 and the design equation is simple and reasonably accurate: R=1.2/I where I is the required current. (See for example the Texas Instruments Linear circuits data book v3 -1989 or no doubt other application notes for this and similar regulators). The regulators are available with max current ratings from I think 100 mA to at least an Amp or more and the cost is low.

Supply +ve to the regulator input (node 1), regulator output to the resistor R (node 2), regulator adjust terminal to the other terminal of R (node 3) with the load connected from node 3 to the power supply ground.

Fig.-1, JFET Constant Current Sink

Design Equations:

Vgs = Vgs(off)*(1-(Id/Idss)^1/2) (eq.1)

Rs = Vgs/Id (eq.2)

Rs = (Vgs(off)/Id)*(1-(Id/Idss)^1/2) (eq.3)

Notes:

1. "(f)^1/2" denotes "square root of (f)".

That's a good approach for some applications, but watch out for the noise. The band gap voltage references in those regulator chips are really noisy. In a voltage regulator, a 10 uF or so bypass at the output is usually enough to kill the noise enough for most applications. But you might not want to put a large capacitor at the output of a current source. I've only used a regulator as a current source a few times, for things like battery chargers where noise doesn't matter, so don't know for sure how bad they might be when hooked up this way. But I do recommend watching out for it if your application can't tolerate a high level of broadband noise.

One datum: 1966 Vauxhall Viva HA, a car I drove off and
on in high school. 12 volts, positive ground. A pain to
put anything electronic in it.

We tried converting it to negative ground (no black boxes
to blow up), but it never ran right (persistent misfiring),
so we put it changed it back to positive ground.

I guess the answer to your question depends on what you are trying to accomplish. Do you want best possible IP3 performance? Do you want best possible sensitivity? Do you want best possible opposite sideband rejection? Do you want minimum power consumption? Are you looking at a simple, medium performance radio?

Hans Summers wrote:
>
> I'm interested in views on the following questions.
>
> Considering a receiver consisting of input tuned circuit, Tayloe detector,
> polyphase audio phasing network, and audio filterting/amplification:

I personally have not used a polyphase audio because my understanding is that they are rather lossy. 40 db? If it is indeed that high, there are engineer consequences to be paid depending on your design goal. In addition, it uses series resistors. Resistors are noise sources that can further degrade the sensitivity of the receiver.

>
> 1. Is an RF amp necessary/desirable ahead of the Tayloe detector? Or am I
> right in thinking that you want to minimise IMD products by doing all
> amplification after the detector?

RF preamplification can improve the receiver sensitivity. I have heard that 40m never has less than -116 dbm of noise. Since 50 ohm noise is about -148 dbm (500 Hz), that means your receiver could be -120 dbm sensitive (28 db noise figure) and still hear all there is to hear on the band. I know that on 20m, one of my -143 dbm receivers (3 db S+N/N MDS) could hear weak but readable cw signals that a -139 dbm receiver could not hear at all. So on some bands, particularly 20m and higher, additional sensitivity is useful.

Think of IM not as a function of just the detector, but rather as the signal saturation of the rf preamp, followed by the detector, followed by the first audio pre-amplifier. The detector can take 4 volts pk-pk if a 5v device is used. As such the first audio pre-amplifier will likely run out of voltage headroom (assuming it has reasonable gain) before the detector will. Thus the audio preamp will be the stage that sets the IP3, not the detector.

You can make a very good estimate of the IM point of the receiver by simply taking maximum possible pk-pk voltage output of the audio preamplifier and factoring out the gain of the rf preamp (if any), the audio preamp gain, and the 1 db loss of the detector, and calculating what input signal level will saturate the audio preamp output. As a

first order estimate, subtract about 23 db from this and you will have a fair estimate of the IP3 of the front end.

More RF gain can give better sensitivity, as long as 4v pk-pk is not exceeded at the detector input, but any gain either in the RF preamp or in the audio preamp will reduce IP3. Without a rf preamp or a rf step up transformer, I figure that -143 dbm sensitivity (5 db NF) is achievable with almost +40 dbm IP3. Playing with the numbers, I think -146.5 dbm (1.5 db NF) is achievable with about +20 dbm IP3.

I have a transceiver that emphasizes low current consumption above all else, and at 11 ma at 12v achieves -137 dbm MDS (350 Hz, 3db S+N/N) and +20 dbm IP3. It is all a big bunch of tradeoffs.

>

> version therefore always superior to any 2x clock design?

I use 4x because it is simple. I don't think there is really any difference in using a 4x frequency source or a 2x frequency source. The stability of both should be about the same. The neat thing is that once you have a frequency source for 4x of 28 MHz, divide by 2 and you have 14 MHz, divide by 2 again and get 7 MHz, etc. However, each "divide by two" also halves the available frequency range.

I have also used dual 1x sources, i.e., a pair of DDSs (AD9851s) initialized to be 90 degrees apart to get the two bits to drive the detector.

> tolerance sensitivity.

The R2 type phasing strip has unity gain which is attractive when the goal is high sensitivity or high IP3. I get a minimum of 45 db of opposite side band rejection, which is pretty good. I understand that the polyphase can do 60 db of rejection, but you have to design around the associated high loss. It is difficult to use a polyphase network and still have a receiver with both good sensitivity and IP3.

> 4. Is amplification needed between the Tayloe detector and the phasing
> network? I understand the input to the phasing network should be low
> impedance, and the phasing network likes to drive a high impedance load at
> its other end. So can one just put 4 unity-gain low noise op-amps before and
> again after the phasing network? In that case all the gain in the receiver

> would be in the subsequent AF stages.

You will need an audio pre-amp with gain if you want to keep the sensitivity intact. For a really noisy band like 80 or 160m, you might not care as long as you are not trying to use a high loss receive antenna such as a beverage. for the same sensitivity, the polyphase network needs more gain (much more?) to overcome the polyphase loss, which will negatively impact the IP3, but on the other hand, the opposite sideband rejection might be 15 db better.

My 1967 MG 1100 had positive ground 12V, and I think some heavy construction equipment and "Mack trucks" had positive ground 12V system. (Supposedly for corrosion prevention? Didn't keep the MG from rusting out!) DC to DC convertors were needed for low tier land mobile 2-way radios, while more expensive models (Motorola MICOR) had positive ground cable options.

We didn't acquire the vehicle until around 1951, some six years after W.W.II when petrol (gasoline) was again available to civilians. Because it was such an unusual vehicle we got to know some of it's history and how and why the engine was changed.
But I know exactly the gas generating systems you are referring to; some local British buses, for example, during W.W.II towed a two wheel trailer behind with such a device on it with a hose going to the engine!
Terry.

J M also said:
> Believe it was easy to convert English positive grounded battery

I believe you are right. No transistors or solid state diodes in them days! Did this inadvertently once, in Canada. My 1962 VW beetle; battery was flat, friendly passer by gave me a boost. Car started, drove home. Next day flat again realized that his boost had been with leads reversed. Boosted again right way this time car ran OK for months! No radio in that car.

One poster mentioned that all the gauges worked OK on a car that had been boost started or battery replaced with the polarity reversed. I think I know why!

We took some gauges out of a scrapped Skoda. Noticed that those that were of the electric indicating type didn't have permanent magnets to provide the magnetic field in them in the manner we are familiar with for galvanometer indicators. Rather the magnetic field was created by a coil. So the indicating circuit (lets say it was the fuel tank level indicator) gave a certain input which was in magnetic opposition to the 'field' coil; but since the field coil was also reversed the indicator worked OK! If the instruments were/had been permanent magnet type the indicators would probably have been hard down at the negative end of the scale! Sound logical?

I miss that old monster hearse; but a wheel came off going past Loch Ness around summer 1953) probably gave the monster a surprise) and although we got it home it was never the same again. And gosh that was

almost 50 years ago and the vehicle was then 27 years old! Wish I had it now though!

I note from your call sign that you were probably one of the 'invaded territories'. And now we got the E.C. (European Community) set to be the biggest trading block in the world by one account? Someone, President George W., I think has already suggested that NAFTA (North American Free Trade Area) and the EC eventually join together to make one huge trading bloc.

Regards Terry.

try www.wires.co.uk they are a division of the Scientific Wire Company & seem to stock nickel-chromium from 0.2 mm down to 0.1 mm. I havent bought anything from them but the site looks promising with 50gm quantities on offer.

4592. SWR Bridge/Detector circuit question

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-01 12:34:59 UTC
From: Henry Gernhardt/Andrea Winship <hcg_alw@earthlink.net>
Message-ID: <3B67F7FD.BFCEC177@earthlink.net>
Source record: 51138

Folks---

I am looking at the schematic of the metering circuit of an MFJ Versa Tuner V. TX power runs through a step-up transformer, the secondary of which is center-tapped. The center tap is sent to ground via a 150pf cap on one side, and a 150pf cap from tap to ground and 15pf variable cap in series with it from the tx line. A 3.3K resistor also shunts to ground. The two legs of the secondary are tied together with a 68 ohm resistor, and two IN34's serve as (I beleive) detectors/rectifiers to drive the fwd/ref metering, which is calibrated on three scales (200WF/R, 2KWF/R, and SWR SET/SWR). On either the forward or reflected side, the cathode of the diodes are shunted to ground with a .01uF cap, obviously for filtering.

My question: How in the heck does this work? My experience with center-tapped transformers has been in the realm of LF AC power, where you use them to get both positive and negative voltages. Could someone explain the theory behind it? Would there be any graphical representations that could help me visualize the current/voltage distributions/flow?

Thanks,

Henry C. Gernhardt, III

Buy an ARRL Handbook (any vintage since 1970) and read all about it.

Consult the ARRL Handbook and read up on reflectometer-type SWR or power meters. What you describe sounds like a very conventional metering circuit.

Perhaps it will help to recall that this circuit is working in a r-f environment with voltage/current waves present in the line in both directions. The intent of the circuitry is to obtain a sample of line current and samples of line voltage. Phase comparisons, etc. are made in the analog circuitry and voltages are developed by the diodes to drive a metering circuit.

> simple, medium performance radio?

My priorities are
1. Simplicity and ease of setting up. This is why I am considering DC rather
than a superhet. This is also why I like the Tayloe detector.
2. Good sideband rejection. For this reason I am interested in 4-path
polyphase as opposed to 2-path audio phasing. I am not worried about the
cost of precision resistors and capacitors for the phasing network, or the
number of stages (6 or even 8).
3. Good IP3
4. Sensitivity (last because I am thinking only of 14MHz max)
I don't care at all about power consumption!

That is interesting. Does anyone know of any references where the losses in
a polyphase network are mentioned? I was not aware that they were considered
lossy. There is a diagram on page 15 of June 1995's QEX in an article titled
"Polyphase Netowrk Calculation using a Vector Analysis Method", which shows
an attenuation of <0.5db in the optimised network, and <6db in a constant
resistance network. Since I am as yet unable to understand the maths in this
article I may be mistaken.

I too worry about the noise introduced by the resistors but I have no feel
for how significant this would be at HF.

I was thinking of a simple Huff & Puff stabilised VFO as per G3DXZ's design,
see the Tech Topics column of RadCom, Sep 2000 (reproduced on my site, see
http://www.hanssummers.com/radio/huffpuff/contents.htm). At 56MHz I would be
able to divide to have a 4x clock for bands 14MHz, 7MHz, 3.5MHz and 1.8MHz.

A lot seems to hinge on the losses of the polyphase network. If I have understood the QEX June 1995 article correctly, these losses can be made very small. I was interested in the 4-path rather than 2-path for the extra sideband suppression, I guess as long as the losses are small this is still valid. Since I am interested in 1.8 - 14MHz only, from what you have said I think I could get away with having no RF preamp, at least at first.

Thanks again for the discussion

I recall in an old ARRL handbook, they had an SWR meter for use with 300 ohm lines, that was made from a section of 300 ohm line and two small light bulbs. You simply taped it to your feedline. One light read forward current, and the other read reverse. Truly ingenious.

I tried a similar approach with RG8 coax, by removing the outer insulation for several feet, and feeding some wires underneath the shield braid. It was based on the ARRL 300 ohm design, and though crude, it did work. Neither of these is suitable for QRP however.

I have a couple of radios (with built in speaker), that have one or both
6/12
and +/- ground switches. AFAIK, all CB radios are/were isolated chassis.

I don't want to stereo type truckers, but some tend to modify them
to exceed design (and legal) specs. The trucks may start with 24V, in
which
case the entire electrical system would be 12V, except for the starter
motor,
which would be 24V, and it would ge that by a unique relay arrangement
that
would connect the batteries in series to start, paralell otherwise.

Henry, download program SWRMETER from website below. It describes how the forward OR reverse power halves of the meter work. I think the centre tapped transformer in your meter allows simple switching between forward and reversed directions. Program also shows how to calculate component values.

In some meters the voltage divider across line is capacitors. In other meters it is resistors. They both work the same way but the capacitors are used in the higher power meters and don't don't get hot.

Download in a few seconds. Not zipped up. Run immediately. Vary components and watch meter reading change.

Source record: 51146
Cross-posted to: rec.antiques.radio+phono,rec.radio.amateur.homebrew

Happy People,

One of the "Radio" departments at work (I think, the group that provides air to ground on company frequencies.) was hauling big box of stuff to the dumpster. I intercepted it, took it home and picked out what I could recognize.

There were a few things in the box that I have no use for, but may be useful to someone. Packaged in sealed cans with older octal socket.
- Motorola Relay 280k1003 24 VDC
- I Think a Low Pass Filter Type 5709-27HPx Made by Price Electric Corp
- Stancor Output Transformer A-8101 Line to Voice Coil

I also got these big heavy, rack mounted Collins radios and something the shop foreman called an "exciter." The exciter is Collins RF Unit 242F-501. It is obviously missing tubes. It does have this kind of interesting 20" long brass box with a slider that's marked in a way that suggests it's used to adjust frequency.

There are also two radios, one obviously incomplete, one with no noticeable missing parts.
The Collins data plate on one says 129.55, the other is blank. The radios each have some small tubes and two big tubes RCA 75-43, 3B28 D with X-ray warnings on the bases.

I'm not interested in messing with this gear. I grabbed the boxes to have a lifetime supply of small piece parts in my hobby shop.

I doubt this is the secret lost Marconi treasure. I am happy to forward some of this stuff to an interested party as long as it doesn't wind up costing me anything.

Email me if you are interested.

Regards
Bruce

Many years ago I simulated a 6 stage polyphase network using PSpice. The losses in "mid-band" were around 15 to 18dB.

(See http://ironbark.bendigo.latrobe.edu.au/~rice/ssb/ssb.html
The polyphase network is figure 4.)

Hello All;

I'm trying to come up with plans / schematics for a transceiver for 10m and maybe 15 and 20m (later). I've been all over the web looking, and it seems homebrewing is a dying art. The local club is no help - all the engineer types are gone. So far, I've found some interesting circuits, but there's always a problem: no toroid data (what core did he use?) or the parts are no longer made (examples like Motorola MC1350P/1590, MC1496, etc.) It's getting very frustrating. Maybe somebody out there can help.

Whatever I end up building, it has to meet these criteria:

1) Cheap - I'm on fixed income and don't have much money, let alone any to spend on " experiments ";

2) Simple - " Keep It Simple Stupid " holds much truth, and improves odds of success;

3) Obtainable - Parts must currently be in production and available in the states in small quantities (what's the sense of building something you can't get replacement parts for ?)

4) Effective - Decent sensitivity and selectivity (to take advantage of this sunspot cycle we're in) in the receiver, and a clean - read >55 dB carrier and opposite sideband suppression, with very low spurious emissions - transmitter that makes 15 - 20 watts PEP output.

5) NO SMD - I have bananas for fingers and have a hard enough time soldering a conventional DIP, let alone a fleaspeck with 20 pins

Have any of you seen such an animal lately? If so please email me. I'm not interested in bells and whistles (good basic performance is more important than flash to me)

In my search, I have found out a few things. Philips Semiconductors Europe) still makes the SA602AN (remember the NE602?) and Ocean State Electronics carries them.

Analog Devices makes a very interesting mixer chip, the AD831AP. Only problem is it's SMD - PQFP 20 pin. Those of you with microscopes for eyes and a knack for microsurgery might want to look at it - amplifiers at in / out, 50 ohm inputs and outputs, etc - a killer chip, if only it came in a DIP. Plus, it's 17 dollars apiece at Newark.

Dan's is still around, and he has Mini - Circuits SBL-1's dirt cheap. I would prefer to work with active devices, for conversion gain (better noise figure, too - the '602 has a 4 dB noise figure [so says Philips])

Problem is, as I said, I can't find a complete circuit, with all repeat all) necessary data for duplication. Anyone care to lend a hand? I could even send you the schematics I've developed - to check my work, perhaps, or tell me if it has a 75% or better chance of working. I can do the math (I think) and I can build it if the math is right, but I can't afford a 200 dollar failure. Please, somebody say they'll take a look.

No, I don't have my license yet. Next local VE session is September sometime. Would like to get at least the receiver up before then for some live morse practice (you can use all the programs and recordings you like, there's no substitute for the real thing). Any old timers or retired RF engineers out there that would like to collaborate on a project?

Please feel free to email me at themohrs@fuse.net. I'll scan my schematics and put them together in a package of JPG's for attachments.

Help me,
Mr. Wizard

Thanks

Mark
Mohr

Source record: 51152

You apply a variable DC voltage through a current limiting resistor. Adjust the voltage so that the capacitor draws a few mA of current. (What you want to avoid is excessive heating of the capacitor.) As the dielectric layer thickens, the current will slowly drop. When it does, increase the voltage again to get the current back up to a few mA. Continue this until you've applied the full rated voltage and the current at that voltage has dropped to a very low level. Or you can use a fixed voltage source equal to the rated capacitor voltage, and vary the resistance to maintain the desired current.

You'll probably find a lot of "dying arts" if the only source of information you're willing to consult is the web. There are a number of QRP clubs that publish excellent magazines containing loads of homebrew projects. Most of them can easily be adapted to higher power levels. Do a web search for G-QRP Club, NorCal (North California QRP Club), and QRP-ARCI, and see what's required to get their journals. I believe all sell back copies.

Although it's getting a bit long in the tooth, the principles and circuits in _Solid State Design for the Radio Amateur_ by DeMaw and Hayward are still relevant. You can get this from the ARRL.

I don't recommend starting with a complete $200 project. Start with simple rigs and work your way up. You'll find lots in the above references.

Mark

First, subscribe to the QRP-L (http://qrp.lehigh.edu/lists/qrp-l/). It's a mailing list of folks who mostly like to build. Hardly a month goes by that some kit doesn't catch the interest of the group, and many folks simply homebrew the kit. About every 6 months or so a new completely homebrew rig shows up. This is a VERY active mailing list and does cover a lot of turf, so you really need to be willing to spend some time with your inbox assistant rules or else a lot of time reading. The traffic is typically >100 messages per day, and although there is some noise, it's not bad.

You've hit on a lot of the common approaches, in fact, if one compares the simple kits, it seems like there are a few common themes throughout.

And the toroid data isn't as much of a problem as you might think. Toroids used in tuned circuits are generally -2's below 10MHz, -6's above, with the exception that -7's are frequently used in VFOs. For transformers, it's generally -43's with an occasional -61. Most times the specs on the transformers are very loose. In the tuned circuits, it's pretty easy to calculate the number of turns if it isn't given.

The MiniCircuits mixers generally aren't used except if the purpose is contesting. 602's work great and don't usually require an RF amplifier. They are, however, subject to pretty bad IM when the band is crowded, so where that's an issue, either a DBM is made up of diodes, or an SBL-1 or similar is used. Plus, the 602 designs generally result in lower power consumption. QRPers (who seem to do most of the building) often also backpack, so low power consumption is a high priority. It's only when receiver performance outweighs power consumption that something other than the 602 is used.

Generally there is a varactor tuned VFO with a single buffer stage. Variable capacitors are large and expensive and hard to find, and require large and expensive reduction drives to make them useable. The varactor solves all these problems and are easily gotten from Dan's or RadioShack.com.

Generally there are IF amps before and/or after the crystal filter. Frequently the crystal filter is designed too sharp and then the Q mucked up with some varactors, giving a degree of control over selectivity.

The product detector is almost always a 602 with a crystal LO, and the audio amp is a 386 or 380 or both. Sometimes there will be an audio filter made of an op amp or two.

An exception to a lot of this is the very popular 2N2/40 (http://www.qsl.net/k8iqy). Jim was constrained to use only 2N2222 active

devices. This makes this particular rig one for which it is unusually easy to get parts. Although the block diagram is pretty standard, the 2N2222 only rule meant that 602's, 380's and the like weren't an option.

The transmitter is pretty much the reverse. The only hard parts tend to be in the output PI network. Even at QRP power levels, voltages can get quite high and often silver mica caps are needed in the output. These can be a little tough to come by, tho RF Parts does have a good selection.

Take a look at the QRP kit makers. Most have schematics on the web and if you compare them, you will find a lot of similarities, and a few different design choices.

Interesting stuff...

The ARRL handbook has had the Norcal Serria in it for the last few
years. The MC1350 AGC amp is obsolete, but I think it can still be
found.

This is a nice rig of medium complexity. This is how I first started
when I began building hombrew rigs.

All the values are there. Just build and test everything one stage at a
time.

Indeed. It is a common fallacy that all information is on
the web. 'taint so!

Other useful references: ARRL and RSGB Handbooks. The
various ARRL collections (QRP Classics, QRP Power, W1FB's
books, etc.). Just about every ham radio book published
in the last 40 years should be helpful. If you're going
to buy just one book, make it _Solid State Design_ - still
a fab book!

If you can't afford to purchase these books (but if not,
how can you afford to be in the Internet?), local public
or university libraries should have at least some of them.

*** I once did firmware for a CPU that had NO direct I/O. None. My CPU
communicated with another CPU and got to use the other CPU's serial port
through a shared-memory interface. Well, that shared memory interface
involved serious software that needed to be debugged. It worked fine with
the ICE, but when I plugged in a real CPU, it sat like a lump and did
NOTHING.

After banging my head against the wall for a couple of weeks, I
remembered that I did have one bit of real I/O - there was a reset line that
my CPU could output to an optional piggyback module. So I hooked a small
speaker up to that line through a resistor. I wrote a quickie character
driver to output morse code. I redirected printf() to that driver. I stuck
debug printfs in the code - print "A" ifyou get here, "B" if you get there,
"C" if you get there...etc.

Plugged in the real CPU, turned on the prototype, it started beeping.
Found the problem in about an hour.

http://homepage.eircom.net/~ei9gq My rig gives 10PEP on
80,40,20,17,10. It can be easily modified to cover other
bands. Be warned! it is not a detailed description
of how to build it, just a pile of schematics and a few
pictures. The source code for the PIC frequency
display/stabiliser (optional) is also on the web site.

73, Happy Homebrewing.

The MC1350 is indeed still available; a number of parts sellers still have them. But best get them now if you want them; they will probably be a lot harder to find in a year. Motorola has transferred the rights to Lansdale Semiconductor (http://www.lansdale.com), but there is no telling when Lansdale will actually produce any parts, or what they will cost.

Once the supply of 1350s dries up, it will force changes to a lot of designs. Lots of radios use them, including the Sierra, the K1, and the K2. I don't know of any simple drop-in replacement; the 1350 has a number of nice characteristics, including high gain and wide-range AGC response. It is a bit noisy, though.

Let's hope Philips doesn't stop making the SA602 (formerly the Signetics NE602); nearly all our current QRP designs will be gone if that happens! Falling back on the previous generation of designs won't help; they mostly used dual-gate MOSFET mixers, which are already extinct. Guess we'd have to move on to the future: switching mixers using VMOS FETs or analog switch ICs, such as Dan Tayloe's design.

As for myself, I'm planning to try out a design based on the AD607 (http://www.analog.com). It's a bit pricey, but it is one of the only receiver subsystem chips that is suitable for a CW or SSB design. (Most of those subsystem chips have limiting IF amps intended for FM use.) And it works at low voltages, so I'm envisioning an ultra-portable rig that runs on a single LiIon cell. I'm hoping that careful design can yield performance in the same neighborhood as a 602-based design, which will be good enough for the class of radio I'm talking about. Surface-mount phobes won't be interested, though - this will probably be an all-SMD design.

By the way, does anyone out there know of distributors who sell LiIon cells? I haven't seen them in any of my catalogs, and web searches haven't yielded any sellers that sell them off the shelf. Buying something packaged, such as a cellphone battery, seems wasteful when I just want the cell inside.

4618. DC0DA 1152MHz osc / VHF-comm 1/78

It's still an expensive pain in the butt, especially for those of us who are starting to need magnifying glasses to work with the tiny stuff. It's impossible to do a project without using circuit boards. And frankly, even if I were rich I couldn't see spending the money on the tools (you'll call them luxuries, I say they're necessary) like the multi-hundred-dollar hot-air soldering/unsoldering tools and vacuum picks.

SMD can be nice for those really big circuits. Anyone who has ever held a 10"x12" circuit board full of TTL knows that. But I can have an NE602 receiver put together and working by the time you're starting to pour developer in a tray.

I'm also convinced that nine out of ten whose first kit or project is SMD will end up deciding they're not cut out for homebrew after all.

Now go on, tell us how much you like unbridging those quad packs with the 0.00001 nanometer centers and three billion pins on a side.

There's an honored place for all the different kinds of construction. It's a real pity to see the parts arena becoming SMD-or-nothing.

I just checked my latest Mouser catalog and 'do tell', they have
components other than SMD for us half-blind old-timers and guys with big
fingers and other has beens from the last century. Those SMD components
are hard as hell to mount on a terminal strip because they keep slipping
thru the holes. Probably just a fad.

For an experimental project that is to be perfected in a breadboard envirinment, the SMD approach is not cost-wise or time-wise effective. After all the bugs are resolved, a semi-final version, followed by a final version, in SMD, is a better approach.Bill W0IYH

I agree absolutely with Bill. Unfortunately, though, this approach is getting harder and harder to do as leaded components disappear from the market. When I first went to work at Tektronix in 1974, there were literally acres of people stuffing leaded components into PC boards. Not long before that, the acres of people were soldering components onto terminal strips. At the same times, home hobbyists were using pretty much the same techniques with the same components. When I left in 1995, the people were long gone, having been replaced by machines plopping SMD components onto boards. A good deal of design was done by modeling -- for that matter, a lot of the circuitry was being put into integrated circuits which were only modeled and not breadboarded at all. As the need for leaded compoments has decreased, manufacturers have cut back production, and a lot of modern components are now available only in SMD or fine-pitch versions. The fundamental problem is that the approach Bill and I prefer is no longer the way it's being done in the commercial world, so as time goes on we can expect it to get harder and harder to find the components and tools we need for this approach. At the moment, we can still follow the old approach by and large, but it keeps getting tougher and tougher. It seems to me the only way we'll be able to keep homebrewing in the future is to adapt ourselves as well as we can to the methods being used in industry. This includes modeling, using SMD components, and even integration. We lack the resources to develop ASICs for individual projects, but things like PIC processors are viable options. We'll have to evolve or die out.

>LA8AK

Yes. I did this a couple of times. Reverse battery, and 'splash' +ve on dynamo field (to reverse the residual magnetism which is needed to get the volts rising). Temperature gauge meters were hot wire, ammeters moving iron, starters series wound - all insensitive to polarity. The only slight drawback was the ignition coil EHT volts. With the correct polarity, the back emf of the primary (about 600V) added to the secondary. With the reversed battery, I understand that it subtracts, and this might be noticeable if ignition is marginal.

> </editorial rant>

I agree. Some SMDs are easier to work with than others though. SOIC style cases have a lead spacing that are half that of DIPs, and I find them quite attractive to build dead-bug style using # 32 gauge enamel wire for hook up wire. They are still easy to work with, and take up much less space. No need to use a special PC board to work with these sized parts.

I have also switched over from using 1/4w to 1/8w resistors because they are a better SOIC size match. At 100/$1 at RadioShack.com, 1/8w resistors are easy to afford. Spend $100 and get all the common values for building.

I have a problem building with the TSSOP which are half again the size of the SOIC or 1/4 the lead spacing of DIPs. I about went blind trying to hook up a pair of AD9851 DDS chips, but succeeded, again deadbug style using # 32 gauge enamel wire for hookup. The AD9851s are not available in anything larger than TSSOP.

Someone on QRPL who evidently did this for a living claims it is easy to work with TSSOP deadbug style when using a fine tip soldering iron and a 20 to 30 power binocular microscope. Anyone know where I can get one cheap? I like to homebrew, and I think I will need it!

> just want the cell inside.

Generally, no - since a LiIon cell can explode with flames if shorted or overly charged, most manufacturers will only allow their distributers to sell them to established OEMs, not small shops or individuals. Liability laws, you know. That's why we can only buy them in packs which then provide all sorts of protection circuitry.

Sure makes it hard for those of us with LiIon powered goodies when the cells expire - a battery pack for my 1995 NEC portable has perhaps $30 of Panasonic 16550 cells in it but you can only buy it for $175 or more. Sigh.

Of course, the Ham / enthusiast approach is to get a cheap (eBay) portable battery pack and strip its cells out. Of course, be careful. We don't read about you in the Silent Keys column!

I had a similar problem with a design in my previous job. I needed to
indicate that the FPGA had been configured correctly by the DSP. We
had a couple of relays so I simply pulsed one of them three times if
the FPGA was OK, otherwise it stuck in a loop pulsing the relay
continuously. We did have a couple of LEDs, but they were driven by
the FPGA.

You might try an auto parts store. I think silicone rubber is sometimes used for gaskets, and they sell material to make your own gaskets with. Certainly some automotive gaskets have to put up with some pretty high temperatures, so they should have something in sheet form that would take it.

I've often thought its ironic that as my eyes are getting middle
aged and losing acuity the parts and pitches are becoming miniscule.
A few years ago I may have been able to cope easier. Now I spend a
large amount of time looking through a binocular microscope.

Hmmm. How many components can dance on the head of a pin?

Phil

Why must it be Windoze? For example, I run Protel AutoTrax (not
free) in a 98SE DOS box without any hitches, and their freebie
EasyTrax aka Easyfree is equally tame. The only significant
difference is that AutoTrax is capable of autorouting, something which
I NEVER would let it do anyway under the 95/5 rule ....

YMMV

Silicon sheeting is manufactured by St Gobain at a facility in New Haven, CT. You should be able to get information at 800-962-2666 regarding retail sources.

Ideas: (royalty free!) A couple of layers of glass cloth impregnated with Silicone RTV ? Same sort of construction made from muffler patching material, i.e., glass cloth and sodium silicate.

Worst comes to worst, he could always attack an old toaster. They tend
to be a fragile ribbon of nicrome though. Over here in Oz the local
electronics shop (Dick Smith) sells 22 gauge nicrome in a pack of about
5 metres for a few dollars.

I've used bathroom heaters, the ones where the radiating elements are
made from ceramic tube with nicrome wound on the outside in a nice
spiral groove (not the quartz tubes with the wire coiled inside), for
dummy loads in high powered audio projects.

Good points, all.

If all people want to do is build yet another radio
based on outmoded 1970s technology, they can do so as
long as NOS leaded parts are available. But if they
want to try anything new, they will have to work with
SMD, whether they like it or not. AD9851 is a good
example of a useful chip that is only available in
SMD, and is not likely - *ever* - to be available any
other way.

If people feel that such components are incompatible
with experiementation, they have two options: whine
about it, or find new ways to experiment. I choose the
latter.

Similarly, if people feel that such components are
incompatible with their eyes or hands, they can whine
about it, or get the equipment they need. Again,
I choose the latter.

I think I see a pattern forming here.

Hi Dick,

Hate to throw you off the track, but if your winding parasitic
suppressors with that nichrome wire, you need to buy the right type of
Nichrome wire.

cheers

I have one of each,bought both new from HRO..non smoker,757
never mobile..747 mobile on temporary occasions...757 has cold solder
joint in power connector..acts like not getting correct amperage but
works after applying pressure to connector...747 works fine in RX but
I get reports of off freq/distorted audio on TX......reasonable offer
gets one or both...757 had MD1 mic and 747 has hand mic.....manuals
included.......e-mail me direct at
ko4qc@mindspring.com

PS:I pay for shipping via UPS ground to 'lower 48'....you pay for
premium shipping...

>
> I've been using one of those common magnified lamps...circular tube
> fluorescent. Will that be ok?

Good lighting is a must, and your lamp may be useful for that purpose. However, I have found the common magnified lamps unsuitable for magnification purposes. I almost need to press the magnifier right up to the circuit, leaving no room for soldering. Even then, the circuit is a bit distorted.

I use a pair of magnifying glasses like the kind used by jewelers. There are many types on the market, and most don't work well for me. Try them on before you buy one! The kind I have found works best for me is call "MagEyes". My wife recently bought me a back up pair from a hobby chain called "Hobby Lobby". It looks like part number 77 0500, normal price $25.99. I believe Hobby Lobby has an email address.

The lenses are 1.6x and 2x. It may be that the main benefit I get out of them is not so much the magnification, but rather the close up vision. I am 44 and since 41 have lost my ability to focus close up on these itty bitty parts. The doctor tells me it is a 40s thing. The use of lots of light helps a bunch.

I use a Weller WCC 100 soldering iron (~$100), which is temperature controlled iron. I normally solder at 700 degrees, going only to 800 degrees for things like soldering double sided PC board boxes (inexpensive custom project chassis!) and for burning enamel off of larger gauge wire such as # 24.

I have several rolls of 0.01" solder that I have picked up for $1 to $2 a one pound roll at hamfests, with either 60/40 or 63/37 mix. My larger 0.031" solder is not as nice, but works OK as well.

Hope this helps.

Eagle CAD from: http://www.cadsoftusa.com for Windows and Linux.
It has all the usual stuff, schematic capture, autorouting, Gerber output,
etc...

The freeware version is quite functional.

From the Eagle CAD doc's.
****
The Light edition has the following limitations:

board area limited to 100x80mm (4x3.2inch), which corresponds to half of a
Eurocard

only two routing layers (Top and Bottom)

a schematic can consist of only one single sheet

There is a program available from www.waldherr.com. This program is a Windows based (95 or greater). He does have a demo version on his website. The name of the program is PIA. It is the best program that I have seen for the money. If you buy the 150 dollar version, you can have up to 8000 pads and 12000 connections. You can create library symbols, and you can autoroute (although who would!). Operation is pretty similar to the 25 thousand dollar route editor that I was using when I worked for Rockwell-Collins (Visula). For any of you that I have sent any of my radio and synthesizer design information to, these designs were done on this program. I know that some of the DOS based programs are pretty good; I used to use one called Layout, written by a Dutch fellow, but this new program.....well, you be the judge, folks!

As a certified "old Fart", I agree with you, but perhaps we should try
to think more positively: as modeling gets better and better, soon we
won't have to build anything at all; we can just MODEL the interaction
of the transceiver we would have built with the interaction of the
transceiver someone else would have built, then turn our computer off
and call it a long day!

Mark, you are making too much of a simple job.

Just get a 1496. Get some resistors and capacitors in the right
ball park and stop worrying about it.

Toroid sizes: low power 1/2", high power 1.5 or 2.0 inch diameter.

If you can't manage from hereon then you are not a person qualified
to undertake the design/build task. Pay somebody else to do it for
you.

Don't expect it to work first time. Mine never did. But you will
have great enjoyment with you failures.

There are many folks who don't have the eyes or the hands to work with SMD components. Does this mean that they should get out of the homebrewing hobby? I don't think so! Most of the component geometry that I am working with is the 0402 size; we will be moving the 0201 size shortly. This doesn't mean that everybody has to do it!

A really good IF amp that is currently available is the Phillips TDA1572. This not only had demod and AGC built in, but it has a buffered, 50 Ohm IF output, for feeding SSB or FM detectors. It has an AGC output that can be adapted to also provide an RF AGC loop. Cost in small quantities is around $2.75. This is the same chip that the AOR7030 uses in its IF strip. It is available in SOIC or DIP form.

Ok This would have to be a newbie question but would any1 know where I can find (on the internet) a site that shows me how to build a 2m fm receiver (with PCP artwork)

Thanks in advance

You could build one using a toroid and a few resistors so I wouldnt pay for it.
Look in the ARRL handbook for a circuit. I used 100 ohm surface mount resistors in parallel to get 50 ohms and it is good to 100 MHz or so. Use a small piece of PCB stock and a knife to cut pads for the components. The surrounding PCB can act as a ground plane. I used a metal boot polish tin to mount the bridge with the 3 connectors (BNC) mounted on the lid and holding the PCB stock. (drill holes in the stock for the connectors). I can get 35dB return loss at 30 MHz which means it is reasonably accurate.
The expensive bits are the signal source and the detector/receiver to estimate loss. (Maybe thats what you are getting for $250) I use a spectrum analyser as the receiver and a sig gen as he source but it would be possible to use a general coverage receiver with an accurate attenuator to calibrate it. I have an attenuator which came out of an ex Telecom piece of gear.

4662. Re: Tayloe Detector / Polyphase SSB questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-04 06:46:26 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3b6b8f95$0$32156@echo-01.iinet.net.au>
Source record: 51058

Hans
I did some work on the polyphase network a few years ago (see Elelctronics and Wireless world March 1994 and Jan 1996)
I found the the 8 pole audio network had about 20 dB loss if it was followed by voltage followers.(high impedance) More importantly perhaps, the out of band losses were much less than in band meaning that the follwoing stages could be overloaded by out of band signals. These factors may limit the receiver dynamic range if you did not carefully design for them. You could reduce losses by summing all ouputs. Sideband suppression was very good at up to 60 dB and you could get an wide effective audio range of 200Hz to10 KHz

I used a single capacitance value and varied the resistors for a RF version of the network which was OK to about 30 MHz. At this frequency strays and circuit tolerances become a problem with only about 20 dB of sideband suppression. Performance was quite good to 10 MHz however. I think I used 10 nF caps with resistors in the range 33-150 ohms, all surface mount to reduce size.
I would be interested to hear of your results
Incidentally I have a VFO stabilizer board based on Eamon Skelton's design at my website

see http://www.iinet.net.au/~richardh/VK6BRO.htm

4663. Homebrew Dials

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-04 12:47:06 UTC
From: xpyttl <xpyttl_nospam@earthling.net>
Message-ID: <e9Sa7.8512$K6.3346961@news2>
Source record: 51059

Last week on QRP-L, someone was asking about a program for drawing homebrew dial faces. I decided to hack something together, and it's been surprisingly popular. As this is a homebrew reflector, it seems like there may be some other folks who want something simpler than playing with a drawing program.

The program is very bare-bones ... there is no ability to save a dial design, no installation program, no manual, no nothing, not even a link on my web page. Just unzip the exe (win32 only), double click, and you will see a dial. Click on the settings menu to change it. You can download it from:

http://hfradio.org/wb8rcr/downloads/Dial.zip

Later, after the typical folks had asked for a Linux version, it occurred to me that a more or less platform-independent version might be possible. The archive below:

http://www.hfradio.org/wb8rcr/downloads/Dial.tar.gz

contains the source and RedHat executable for a similar program that reads a script describing the dial and outputs PostScript. If you have a PostScript printer or GhostScript you're in business on Linux. For other platforms, you will need to compile the source, but I've tried to avoid any platform-specific quirks.

Enjoy

Does anyone have a schematic of an 80-15 meter amp using a pair of 813 tubes
in grounded grid configuration?
I have a pair of 813's and would like to build an amp around them.

Look in older ARRL handbooks 1960s 1970s and you should find several. It was a very common amp during that era.

Looks like a great idea, but I'm not seeing a sample dial to start with
or a way to create one from scratch? Pse explain.

That's come up before.

The image on the screen is roughly 3 times the size of the one on your printer, depending on the printer. On some screens, it is initially way off to the right (and possibly down) from the display area of the window. Simply scroll around in the window and it will be there. Alternatively, make the radius larger so it takes more space.

==========
Dear xpyttl, its no surprise to me its so popular. Few minutes back I downloaded it. A lovely little program. 5 minutes practice is enough to become an expert. Print it and cut it out with scissors.

One suggestion - do an outer circle for cutting round. Doesn't matter much because a pencil and compass around the centre marker is easy enough.

Got any more like that ?

Source record: 51072

Hi

Have been interested in obtaining a goniometer for some time, but it seems that I started the search over 10 years too late. However, tonight I visited a friend and got a goniometer which seems to be integrated into a receiver.

Does somebody have any info on this receiver? It looks rather English, but it is made in Japan, covers 200kHz to 13.5MHz in 5 bands. Scales for frequency and compass direction. It operates on A1, A2, A3 and SSB, and has some xtal positions - possibly for some IF function. It is operated from 24VDC

I want to thank all those who responded so soon after my first posting, requesting help with homebrewing an HF SSB / CW rig. In particular, Brad and John come to mind. I'd have to close this window and open another to find the rest, but you know who you are.

The project is coming along - I've pretty much settled on a universal SSB/CW transceiver module using diode ring mixers and discrete transistors in bidirectional amplifiers. Only switching is 12 volts to go from TX to RX and back. All broadbanded, uses stock filters from Hayward/DeMaw tables. Just need the heterodyne VFO chain to get from 5 - 5.5 mhz VFO to 20 - 20.5 mhz
injection (using 8 mhz IF, ladder filter built with surplus cpu clock crystals.)
I hope to have the design finished, maybe even a prototype, by Xmas.

Someone said Dan Tayloe responded to my first message, and that he is sort of the " king " of homebrewing ? Didn't get an email from him, nor do I see a post here. Did I miss something somewhere ?

Again, thank you for the advice and encouragement ; I'll keep you all posted.
The Japanese can keep their $ 3000 radios, thank you.

TNX / 73

I couldn't agree more. The point is that much DOS software runs quite
happily under MOST flavours of Windoze, so DOS software should meet
the requirement unless there is something more to the request.

Mark:

It sounds like a very ambitious project, and quite a bit of fun. I
first started doing a lot of homebrew stuff when I moved from Chicago to
Phoenix eight years ago and found that my Kenwood TS820 was no longer
functional. Long story. It was a very bad moving experience.

As a result, I decided to build my own rigs rather than fix or replace
what I had.

My first radio was simply too complex. I gave up after several months
as it was taking too long. Projects are kind of like that. If it is
too much all at once, you may simply decide to bag it all before you get
done. Part of this is that you may get a good ways into the project,
and discover that you made a really bad design decision along the way
(like I did). At this point, it can be too difficult to go back and
modify all that you have done.

It is often better to do a series of projects that are of increasing
complexity, so you get a chance to learn from what you have done, and do
better the next time around.

If you really want to do the SSB project. I suggest simply working on
getting the cw transmitter going first and having some fun with it.
Later, you can modify it to do cw and SSB both. Next, you can build a
companion receiver making use of the common 20 MHz LO chain. However, to
keep things simple, I would suggest using separate crystal filters for
transmit and receive. Filters are very cheap when you match crystals

and build your own.

The receiver will be the most complex part of your transceiver, so if you build in a modular form, you can start simple and gradually make your receiver more complex as needed. I once built the IF section of a complex "hanging" AGC receiver from a older ARRL handbook for a 30m receiver. It seemed to work really well, but it also took a very long time to complete. This was my second project after giving up on my first project, an all band transceiver. I almost gave up on this second project also. I suggest starting with a simple superhet design and work on improving it section by section.

One other little note: Mixing harmonics can cause a lot of problems. It sounds like you are going to mix a 5 MHz VFO with a 15 MHz crystal to get 20 MHz, then beat with a 8 MHz IF to get 28 MHz. 15 MHz is the third harmonic of 5 MHz, so those two will not mix well together. You will end up with some 20 MHz that is 1x VFO + 15 MHz (crystal) = 20 MHz and some that is 1x VFO + 3x VFO = 20 MHz. Not good. You will be tuning the receiver (or transmitter) on two different frequencies at the same time, one at a 1x tuning rate (5 MHz VFO + 15 MHz crystal), and one at a 4x rate (4x 5 MHz VFO).

A good mix is a crystal that is 2.5x the VFO. In this case, 14.318 MHz (a stock crystal frequency) and a VFO starting at 5.618 MHz may work better. The fifth harmonic of the VFO will be in the 28 MHz range, but will be at least 80 KHz higher than where the receiver is tuned. You will end up with a receiver birdie at 2x 14.318 MHz (28.636 MHz), but I think that is outside your intended tuning range.

Also, a transceiver with 500 KHz of tuning range will be a bit twitchy to tune. You may want to do a 500 KHz band set dial, with 10:1 drive reduction (5 turns total for most tuning capacitors), and a small 10 KHz band spread knob for fine tuning adjustments. I have found that 10-20 KHz per revolution is a good rate for a nice receiver, and you will not get that with a 10:1 vernier and 500 KHz of tuning bandwidth. That will be especially true as the tuning rate changes over the 500 KHz range. Maybe you might simply start with a smaller tuning range.

Good Luck! Home brewing can be a lot of fun!

4685. thyristor firing on transients in power supply?

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-06 02:30:13 UTC
From: lagagnon@fakesprint.ca
Message-ID: <3b6dfe27.71929@news.sprint.ca>
Source record: 51081
Cross-posted to: sci.electronics.basics,rec.radio.amateur.homebrew

I have completed building a 13volt, 25 amp power supply. I have included an overvoltage protection circuit (design from the Art of Electronics). This is basically a 15 volt zener diode, to the gate of a 25 amp thyristor (SCR). The diode goes to ground through a 150 ohm resistor and there is a 0.1uF bypass cap to try to limit transients from firing the thyristor. There is a 25 amp fuse in front of the SCR.

The supply works great without the protection circuit. However, with the protection circuit inline the SCR often fires and the fuse (fast blow) thus blows when certain, even small loads are placed on the supply. One of the loads is a DSP filter, drawing less than 1 amp. but this load has a voltage spike (as seen on a scope) the moment it is turned on. I have attempted to limit any RF spikes by putting clamp-on ferrites onto the power cords, but with limited success.

Without major modification (due to heat sink placement) I am unable to get the 0.1uF bypass capacitor closer than 4 inches to the SCR gate and I wonder whether it would help to get one closer? Any other ideas to help limit the transients from firing the SCR would be gratefully appreciated.

There are all sorts of things you can do to delay the firing of the
SCR (the first of which is to put the filter cap directly on the leads
of the SCR). But if it is worth having, then it should be pretty
fast, or it will only close the barn door after the horse has escaped,
so to speak.

I would like to see the schematic of your regulator circuit (including
the crowbar) to help you figure out why it is producing voltage
transients with small load swings. You are fighting the symptom, not
the disease.
Okay, I have used up all my lame metaphors for now. :)

In cable tv amplifiers, we often have similar spikes in the line equipment. One cure that has been very effective is using what the vendor calls a 'transzorb'. I always thought it was simply a zener, but they tell me there's more to it than that. I've heard it referred to as a 'surge-clamping diode'.
I have one in my hand here and its a Motorola 1N6281A which I believe is a 27 volt one. It would be connected across the output of the 24v DC power supply. Since I'm not well-versed enough to explain anything about it, maybe you can look up the number and see if that series might offer an easy fix. It certainly works in our amplifiers by bringing input fuse blowing down to almost nil.
Good luck,
Bill

Dan Tayloe's comments about mixing spurs being possible problems is worth thinking about. I built a homebrew 40 meter CW that was great and I planned to make it into a transciever until I finished the Rx and found a spur right in the middle of 40 meters !!

It was a harmonic of my vfo mixing with a harmonic of my bfo... And really hard to chase out of the rig.

So, I wrote an analysis program and turned it loose on calculating If freqs/VFO and so on and the number of BAD choices was astonishing.

I am going to build a new single band radio that won't have this spur. I do learn, eventually.

==========

However, all this convinced me that a multiband radio was going to wait until after I get a single band up and running properly. Multiband adds 'way too much to think about as a first project.

Not impossible by any means, but very complex with one heck of a lot of possible gotcha's that would make it more likely to have design troubles....

Be very careful where you connect the 150 ohm resistor and capacitor. If you can't put them right at the SCR, don't connect them to ground where they're placed. Instead, run a wire from them to the SCR and connect their ground sides directly to the SCR anode terminal. Otherwise, they could be aggravating the problem.

You should also take a look at where your output voltage sensing is done. The sense inputs should connect directly to the output. Failure to do this could be the cause of the voltage jump when you turn on the DSP filter. Or there might be something else about your regulator circuit that's causing it to respond to a current increase by producing a voltage spike. This indicates some instability in the regulator circuit.

You probably should find and cure whatever's causing the voltage spike rather than try to prevent your overvoltage circuit from firing when it happens.

A diode in series with the DSP unit (between it and the supply)
might help. This would prevent the voltage spike generated by the
DSP (probably by a choke in its input filter) from getting back into
the power supply.

Source record: 51093

Guys, I would like some Linux hack out there to take a look at the latest mutation of the Dial program - this one does panels.

If some brave soul would take a look at:

http://hfradio.org/wb8rcr/downloads/Panel-1.6.tar.gz

and let me know if he can make it work. This business of doing an entire panel is quite a bit more involved than just a dial, so I'm not so convinced that the script model will work. Well, it will work for me <g>

Anyway, this is a big step up (IMO) in utility. At this point, only the platform-independent version is out there. If there's some interest, I'll at least recompile this one for Win32, but a full GUI version like the Windows version of Dial is at least a month away, if ever.

By the way, I was surprised to see >400 downloads of the Dial program in the past week. Still nothing like the rate QSLMaker continues to get downloaded, but for something with such a narrow audience...

A similar question came up some years back, and shortly after I was going through old QSTs and someone had a "Hints & Kinks" about increasing the drive f4rom an HG-10. I can't remember the solution, or the reasoing, but it would have been 25 or more years ago.

One solution you would see is sort of a step up transformer at the crystal socket end. The coax would be the low impedance point, and the high impedance would feed the rig. They tended to use tuned circuits for this. Details should be found in old ARRL Handbooks.

I used an HG10B to drive a T50 for many years. I don't recall having to make any changes to either. Are you sure both are working ok? Have you tried inverting the VFO plug that you're plugging into the front of the T50? Does the T50 work OK with a crystal?

Humph. Attitudes such as that do little to serve the cause of
experimentation, in my humble opinion. Sounds like the wingnuts that
used to tell me that if I weren't on 1215 MHz, I wasn't really using
Amateur Radio.

I've developed a more tolerant attitude toward those who have problems
with components being "incompatible with their eyes or hands" since I
passed 40 and my vision isn't quite what it used to be. It's a
different story when you bend over that radio and it's not as clear as
it was a few years ago.

There should be room for all experimenters, folks. I still do most of
mine with tubes!

Hi guys,
Thanks for the replies. I belive that both the T-50 and the HG-10 are operating ok. The manual for the T-50 states a required drive level that is higher than the speced output of the HG-10.

Another person posted that replacing the 560uH choke in the plate ckt of the osc with a 1mH, increased the output. He also mentioned that this mod appeared in an old "Hints & Kinks". I'm going to give this a try.

Thanks again!

You probably need more output voltage and a higher impedance. Try winding a toroid balun with a step up ratio. Maybe 2.25 to 1 or 4 to 1 as a starter.

cheers

Hey gang, a couple of things I overlooked on the 1.6 Linux version of Panel:

- I forgot to handle color for text
- I included a lame example file, thinking I had used a better one

So these are fixed in the 1.9 archive, and while I was at it, I beefed up
the README a little.

http://hfradio.org/wb8rcr/downloads/Panel-1.9.tar.gz

Some folks have asked for the Win32 build, so that will probably be next.
Sorry I don't have DJGPP installed for the DOS folks.

Oh yes, if you make up some neat looking panels, pass them along.

Not sure without more info about those transformers. However a reflex
radio circuit is one the uses one stage to amplify the radio frequency
then the audio frequency is fed back and amplified using the same tube
or transistor.

I once rigged a 555 circuit as a retriggerable monostable, triggered it with the audio of one radio and used it as the PTT for a second on another band to rig an emergency crossband repeater. Took ten minutes, worked fine. Natch, we had to ID manually.

...and in a subsequent post went on to say:

: If all people want to do is build yet another radio
: based on outmoded 1970s technology, they can do so as
: long as NOS leaded parts are available. But if they
: want to try anything new, they will have to work with
: SMD, whether they like it or not. AD9851 is a good
: example of a useful chip that is only available in
: SMD, and is not likely - *ever* - to be available any
: other way.

This certainly isn't absolutely true. During the reigns of various now "outmoded" technologies, people didn't think of every possible circuit or variation. Experimenters who continue to dabble with old technologies continue to include among their numbers some who manage from time to time to come up with something innovative. Only those who share their interests take notice, 'tis true...but they manage to have very fascinating experiences as experimenters, even without being on the leading edge. They may not work with things which are new, but that doesn't keep some of them from trying something new, and sometimes, succeeding brilliantly.

Of course, few of us are truly innovators, or are innovative in only some narrow way. Most of us copy circuits that have already been designed, tried, and published (if perhaps only informally) by someone else. I fail to see anything more noble in the copying of a circuit which someone else designed six months ago than in copying one designed six decades ago. For those who truly are innovative, I fail to see anything less noble about polishing older technologies than polishing newer ones.

Things become "outmoded" because they are no longer the best choice--for commercial concerns. The commercial focus does dominate where "what's new" is concerned, but the focus of those who are in the game to market to the masses and make a quick profit need not determine the constraints under which all of us pursue our own fancies as amateurs. As amateurs (who, by definition, are in it for the love of it, rather than to make a profit) we have the freedom to weigh a wide variety of factors in choosing what to pursue personally. We're free to

value non-economic factors as highly as economic factors. We're free to consider even our economic context in a broad sense, weighing factors such as our time invested and our ability to scrounge for parts in addition to more purely financial concerns, and perhaps weighing those factors very differently from how someone else might. With our unique goals (almost as varied as the personalities of the cross-section of our society we hams represent), unique opportunities and unique talents, we're able as individuals to pursue whatever each of us will find most satisfying. We may easily do so without compromising our duty to society, for it is this very diversity which allows us to meet our obligations like no one else can. An amateur community which, collectively, has mastered a broad foundation of technologies, philosophies and approaches can certainly contribute more richly than if we all focused in the same direction--in whatever direction industry might happen to lead us.

: If people feel that such components are incompatible
: with experiementation, they have two options: whine
: about it, or find new ways to experiment. I choose the
: latter.

Another option would be to choose to experiment with whatever they can find our scrounge which better suits their individual preferences. Many choose to do just that.

: Similarly, if people feel that such components are
: incompatible with their eyes or hands, they can whine
: about it, or get the equipment they need. Again,
: I choose the latter.

Another option would be to choose to experiment with materials which they do not find to be such a strain. Many choose to do just that.

Amateur radio is well served by those who strive to help define the leading edge, and by those who strive to master it as it develops. Amateur radio is also well served by those who strive to master older technologies, and by a population skilled in the use of equipment and techniques from as wide a base as possible. Amateur radio is well served by those who go where no one has gone before, whether they are designing leading edge technologies out of thin air, or improving technologies we've been comfortable with for a long time.

Amateur radio is perhaps not so well served by expressions of impatience with those who choose another path, and is certainly not well served by our characterizing each other's expressions of preferences as "whining". It's good to work hard to master whatever approach one chooses,

and to keep abreast of associated developments, however rapidly they may evolve, and even to promote the advantages of one's chosen approach at every opportunity--but it's quite another thing altogether to take every opportunity to criticize anyone who's chosen to focus on some other approach instead.

73,
Jim WB5UDE

4716. 17mtr DSB: AF amp cramps

Newsgroup: rec.radio.amateur.homebrew
Date: 2001-08-08 09:56:26 UTC
From: n2cqr@clix.pt
Message-ID: <3b710c6f.1860694@news.clix.pt>
Source record: 51013

I've been trying to add more AF gain to my direct conversion RX for 17. I have a 100db, three transistor (2n2222a) direct coupled amp similar to the one from SSD. (See my web page for the schematic -- URL in the sig below.) This amp works very well -- it is very quiet and does not take off on me. I have a grounded gate RF amp (about 10 db) ahead of the mixer. I think there is about 8 db of loss in the mixer.

I know the RX would work better with more AF gain. When I plug a little amplified computer speaker in the AF out from the 100 deb amp, I can turn the RF gain very low and the whole system seems to work better.

I tried adding an MPF102 amp stage ahead of the 100 db amp. It added far too much noise. Then I tried an additional 2n2222a stage AFTER the 100 db amp. Again, way too noisy. Today I built a 40 db amp out of the ARRL data book. Again, too much noise.

What am I doing wrong here? Am I proving that there is wisdom in the decision to go with LM386s and other ICs as AF amps? Is it really this difficult to get sufficient AF gain in a DC RX using discrete transistors and simple circuits? Why is it that the 100 db amp is so quiet and works so well, while the others add so much noise?

BTW: I had some AM detection problems with a RADIO EXTERIOR de ESPANA SW broadcast on 17.7 Mhz. I put a series tuned circuit between the RF and ground. A bit of tweaking knocked the SW signal down nicely while leaving 17 meters intact.

Don't get me wrong -- the RX is working nicely already. When I talk to Amadeus, CT2HGL, I can hear his parakeets in the background. And I can hear the seagulls outside G3IUE's window! Recent DX: 4Z4, 9K2, Shettland Islands....

I _hate_ the LM386, it is a noisy and overpriced device IMO. I prefer to replace it with a LF353 and two transistors, using one of the op-amps and the transistor pair as a unity-gain current amplifier, and the other op-amp as a moderate voltage amp (often a gentle LPF too).

Your 100dB amp is quiet probably because of the distributed gain, each device is basied at quite low current (well the first one is) which helps keep the noise down.

You could try boosting the performance of the transistor amps by using current mirror collector loads instead of just plain old resistors. With BC550 devices a very nice low noise AF preamp can be built. I've even seen people parallel them to reduce the noise figure.

There is nothing wrong with using those "old black things with three legs", while it results in a much larger footprint, you can make higher performance circuits cheaper and with a wider range of voltage and current options than are available with IC op-amps.

Besides it is more fun :)

Calling a device that sells for under $1 "overpriced" seems to be overstating your case a bit. On the Digi-Key web site, the lowest output version of the LM386 is about the same price as the LF353, and you don't need the transistors and as many other components. The higher output LM386 versions are a bit more, but still under $1.

The LM386 is an inexpensive, simple to use amplifier that is good enough for many applications; that's why it's popular. If you want something better (lower noise, flatter frequency response, whatever), by all means use something else.

Indeed, I just checked, it has come down in price since I last
purchased it.

In Australian prices it is about the same as you quote ($2 or so), and
at Jaycar the LF353 is actually slightly more than the 1 watt version of
the LM386. In the past it has been up to $5 for the 1 watt version, so
it has come down some this year.

The biggest problem I have with it is the noise.

I can't argue that it isn't simple and easy to get going though.

> The polyphase network is figure 4.)

Thanks for the link. I'm going to try simulate a polyphase network myself,
trying the geometric progression of resistor values as shown in the QEX
article, to see if it really does reduce the losses. I'll let you know what
I find.

I was interested in the single capacitance value, because resistors are
available more accurately than capacitors, so I thought of purchasing a
whole load of same-value capacitors and matching them in 4's. But then I
read the QEX article which recommends that to minimise losses in the
network, one should use a geometric progression of resistance values from
stage to stage. This implies varying capacitances too.

How sadly true. When I went to a local "truck farmer" to buy a 60#
bucket of honey (the trachea mites got all my hives!), the farmer saw
my ham-radio license plate and he asked if I could repair a beloved old
Zenith TUBE radio that had been in his family for many, many years. He
said "I've taken it to all of the 'electronic repair' shops in town, and
no one would even touch it!"

I haven't looked at it yet, but I will. Fortunately, I still have a
tube tester, signal generator, and signal tracer, and, even MORE
fortunately, my eyes are still good enough to see the parts!

even tube technology has improved during the last 40 years, but
reading posters on some audio and boatanchor groups indicate
applications of simple 12AX7 amplifiers I wouldn't care for in 1960

One interesting thing is to judge some old receiver designs, compare
different articles from 1950-1970 and see if you agree with the
modifications proposed, often they are doubtful, wrong application
causing more changes than really neccessary. Often simpler approaches
would be just as efficient

IMHO, junk is still junk regardless of the price. I've never understood
the LM386's popularity.

The LM380 is a much better choice for low-power AF power
amplification... easier to use, too.

For low-noise opamps, try something like an OP27.

It's not really a bad thing to do. There are several low-noise audio preamp type ICs, from what I'm told (I bought a fistful but haven't had a chance to test them). The NE5534A is rated 4.5 nV per root Hertz input noise at 1 KHz, so output noise would be 142 nV times whatever gain you use for the op amp stage.

> Why is it that the 100 db amp is so
> quiet and works so well, while the others add so much noise?

You DO realize that nearly anything you put in front of OR after a 100 dB amp will further enhance the noise that's already coming out of the mixer, *and* the noise generated by the first stage, right? (I'm sure you do, but one has to ask.)

The line of sight path loss equation I've been given (and found) is

a= 32.5 + 20logD(km) + 20logF(MHz) (dB)

I understand the 20logD term, it is proportional to the area of the wave front as the distabnce expands.,but what is the physucal explanation of the 20lofF term?

If I have 1 W isotropically radiated power why is the 10 Mhz signal stronger than a 1W 1 Ghz signal?

It can't be just atmospheric absorbtion as that would have both frequency and Distance terms, and the I believe that the distance term is fully spoken for for by the spherical wave front area/distance calculation.

Source record: 51024

The second term is a consequence of the fraction of the wave front
intercepted at different frequencies by antennas having the same gain.

Consider a parbolic reflector antenna with a cross sectional area of 10
square wavelengths at one frequency f1, and another with a cross
sectional area of 10 square wavelengths at twice that frequency, or 2f1.
Both antennas will have the same gain at their respective frequencies.
Yet the first (low frequency) antenna will have four times the cross
sectional area, in square meters, as the second one. Consequently, the
first antenna will intercept four times as much power from the incoming
wave as the second one does. This assumes that the incoming power is
distributed evenly over an area at least equal to that of the larger
antenna.

Paul Trying to understand.

Looks like my recent post in this ng ...

As an adjunct to understanding this equation, I often group the F and
D terms:

a= 32.5 + 20logFD (km,MHz) (dB)

What is FD? Barring scaling factors (like c), the number of WAVELENGTHS between isotropic source/detector. Maybe it becomes more intuitive that way - loss proportional to the number of wavelengths travelled. Maybe that doesn't work for you.

As an aside, I have always had the greatest respect for Roy's work, but I found his post a little obfuscating. OTOH, the thing you WILL observe from his analogy/expansion is that the "pathloss" between (say) parabolic dishes of a certain capture area is independent of frequency because their capture (and hence gain) goes up as the area in "square wavelengths" i.e. -20logF. See the next para.

If you want attenuation between non-isotropic antennae (i.e. real/achievable ones) the equation becomes

a = 32.5 + 20logD(km) + 20logF(MHz) - G1(dBi) -G2(dBi) (dB)

where the G terms are the gain over isotropic of the antennae at each end of the circuit.

The pathloss equation can be expanded to incorporate more terms depending on what you are trying to achieve/measure. We often used it in a composite form to measure system figure of merit, which really is a pthloss equation with all other factors incorporated eg gain of antennae, feeder losses, filter attenuation, Tx power and Rx usable sensitivity or required siglevel etc.

I hope this has helped in some small way.

Peter

It's solely to account for the size (capture area) of the receiver antenna.
For a given gain, higher frequency antennae are smaller (and there's no
such thing as a free lunch ;-).

The transmit antenna (ideally) radiates 100% of its input no matter what
the frequency or its size. (The energy has to come out somewhere ;-)
Just apply "control volume" theory, popular in fluid mechanics, and
conservation of energy.

No, if it were independent of frequency, there would be no F term. The pathloss depends on the gain of the transmitting antenna, the effective area of the receiving antenna and the distance between them. However, the gain of a parabolic dish is dependent on frequency (4*pi*A/wavelength squared), which gives the -20logF term.

Pathloss = Gt*Ar/(4*pi*R^2) = Gt*Gr*lambda^2(16*pi^2*R^2)

Thanks, Bob, I am aware of the relationships. Maybe I expressed it poorly. The increase in gain of the constant area antenna offsets the logF term from the naked (isotropic) case.

Simply put, it's because the receiving antenna's size has been
defined in terms of wavelengths, rather than in feet or meters.

I need help identifying a meter shunt resistor on an AEA LA-30 amplifier. I picked it up unworking and immediately found that the plate current meter shunt is blown. If anyone has or knows someone with one of these amps I need to know the value of this resistor. It is R39 on the schematic but no value is given. It is located on the top circuit board in front of the transformer. It is the resistor in front of and parallel to the 12 pin edge connector.

We are both thinking the same thing, but no, I was the one who
expressed it poorly (one should never do math late at night). In
reality the term "pathloss" is not applicable in the equation I wrote
above. It should only be used where the power transfer is expressed as
a logarithm, not when showing it by a power ratio and is really a
convenient grouping of several of the terms of the equation. I guess
it has been too many years since I have thought about such things.
Anyway, further thinking on the subject has cleared away some of the
cobwebs in my mind (I didn't think I had been retired **THAT** long!)

Increasing antenna gain will (obviously) increase the signal, not
decrease it. What I expressed above is not "pathloss" but the ratio of
Pr/Pt. Expressing both antennas as effective area interestingly gives
the result Pr/Pt = At*Ar/(lambda^2*R^2), which shows that the amount of
power received actually increases with frequency for this case. The
gain goes up as frequency squared, but so does the effective area (in
"square wavelengths" of the receiving antenna.

If you transmit from an isotropic antenna (or any antenna whose gain is frequency-independent) and receive on an aperture of fixed area, the Pr/Pt ratio is independent of frequency (in a vacuum, at least).
